

1 MR. SHETTEL: That should be perhaps part
2 of the historical record, and it would be very
3 interesting.

4 MR. LEE: Well, I know as the authority
5 responsible for regulating water use, I think that
6 might be an issue that the State of Nevada may have a
7 better sense for. I am somewhat removed from the
8 data.

9 MR. SHETTEL: That is probably part of the
10 State Engineer's database, perhaps. I don't know
11 personally. Just an idea.

12 MR. LEE: Thank you.

13 CHAIRMAN HORNBERGER: Thanks a lot, Mike.
14 We have had enough feedback to lead you to your next
15 three papers. I think we are going to proceed, and I
16 believe everyone is here. We know that our speaker is
17 here.

18 And so we have a program next that is for
19 a DOE scientific update, and we have several things,
20 or two things, two main things that we are going to
21 consider this afternoon.

22 The first is an update on the Chlorine 36,
23 and I think probably everybody knows that the finding
24 of Chlorine 36 at the repository in Horizon at least
25 five years ago led to some reappraisal of fast flow

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 paths, and potential fast flow paths to the repository
2 arising.

3 And later there was some -- a different
4 laboratory had done some analyses and there is now
5 some work trying to work towards a resolution of
6 differences that were observed.

7 So, Zell Peterman is going to give us an
8 update.

9 DR. PETERMAN: Let me mention before I
10 start that there is a significant part of the Chlorine
11 36 validation team here today. Bob Robeck from Los
12 Alamos has taken over the work down there, and Greg
13 Nimz from Livermore, who actually does the Chlorine 36
14 analyses, and my colleague from Denver, Leonid
15 Neymark, who had been heavily involved in the design
16 and the sensitize design and the sensitize related to
17 the validation project.

18 The first slide, I gave something similar
19 to this several weeks ago to the BSE Project Oversight
20 Board, and Bob Thorsen (phonetic) observed that I had
21 15 pages of history and no conclusions regarding the
22 validation project, and nothing has really changed.

23 But let me just jump to the conclusions
24 first, and then work our way through this history. We
25 thought it was important to try to give a historical

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealgross.com

1 perspective as we think we understand it.

2 And over the last 3 years, we have
3 generated a lot of data, and we have given a lot of
4 thought on how to try to validate the work. We have
5 done a number of experiments, and we have a lot of
6 information.

7 And our immediate goal is to sensitize and
8 integrate all these datasets in to a report that is
9 due in December. And that in that report that after
10 doing all of this, and really having time to think
11 about the data, we will develop a path forward. Right
12 now we don't have that. The report is our path
13 forward.

14 But there will be in that report
15 presumably a path forward that leads to hopefully some
16 sort of resolution. And that is kind of where we are,
17 and let me just go through this.

18 I have a lot of slides, and I don't want
19 to go and read every bullet, but let me just try to
20 summarize. Sometime in early Fiscal Year '96, when
21 the ESF was being constructed, there were two studies
22 that were started.

23 One was Chlorine 36, and the other was a
24 study of fracture minerals, fracture minerals being
25 the only physical evidence of percolation through the

1 unsaturated zone at Yucca Mountain.

2 Los Alamos conducted the Chlorine 36 work,
3 and USGS conducted the fracture mineral study, and
4 basically we both sort of followed the TBM as it made
5 a tunnel and collected our respective samples. Next
6 slide, please.

7 Early on when it was evident when elevated
8 Chlorine 36 values were found, we had a meeting in
9 Denver, and the Los Alamos' folks, and the Denver
10 folks, and we really struggled with what this meant,
11 and how we were going to validate it.

12 We talked about doing deturium, technesium
13 99, and iodine 129. There was a very early attempt by
14 the USGS to look for tritium and that pretty much
15 failed because samples were collected from the tunnel
16 walls, and those tunnel walls had been saturated with
17 construction water. Next slide.

18 The Chlorine 36 worked and continued to
19 the ESF, and into the ACRB as it is referred to.
20 Technesium didn't really get off the ground, and it is
21 really a tuff thing to do.

22 The work on the fracture minerals, we
23 developed a spectrum, a dataset, for the uranium
24 series that ranged from a few thousand years, a few
25 tens-of-thousands of years for the youngest, outer-

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

1 most materials, to well over a half-a-million years
2 for the older material.

3 And then this evolved into a uranium lead-
4 dating system, which now pushes the formation of the
5 older parts of the fracture minerals back to 10 or 11
6 million years, within a million years or so of when
7 the tuffs were formed. Next slide.

8 In 1999, and I think it actually started in
9 late '98, the DOE asked the USGS to organize a
10 validation project that could independently verify the
11 presence of bomb pulse Chlorine 36 or not in the
12 exploratory studies facility.

13 The final proposal, and what we put
14 together, involved the USGS, Lawrence, Livermore, and
15 AECL, and Los Alamos, as an oversight -- to provide
16 oversight for the validation work.

17 The first organizational meeting was held
18 in the spring of 1999. Next slide. This was the
19 dataset at that time that we were asked to look at and
20 basically on the wire access to the Chlorine 36 over
21 chloride ratio, times 10 to the minus 15, and it says
22 maximum twice the same.

23 And that was considered anything above
24 that line was considered to be bomb pulse. The little
25 XXs is just distance from the north portal through the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 ESF, and the anomaly in the middle there is associated
2 with the Sundance Fault.

3 And we refer to that as the Sundance
4 Anomaly. And just another point, there is an anomaly
5 to the left of that that is composed of about five
6 samples, and that is the drill hole life feature. So
7 that is kind of what we were looking at. The next
8 slide, please.

9 So we tried to design a sampling from it,
10 and we decided to look at the Sundance anomaly, and
11 the Drill Hole Wash anomaly. And we went to the
12 tunnel, and we looked at all of the sample sites,
13 sites that had been sampled by Los Alamos.

14 And we looked at all three maps to assess
15 fracture spacing and that sort of thing from the
16 Bureau of Reclamation mapping. Because of the -- the
17 dataset that you just saw was developed from samples
18 that were largely collected from the right rib of the
19 ESF, the lower quarter, because a lot of them were
20 collected by jackhammer.

21 And by the time that the validation work
22 started, that lower quarter of the ESF had been washed
23 down so many times to clean walls or control dust,
24 that it was decided that it decided that we were not
25 going to try to collect samples from there again. So

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 the next slide, please.

2 So it was decided that we would build four
3 meter long bore holes, dry drill 50 of these, and 40
4 spaced along the Sundance anomaly and 10 spaced along
5 the drill hole wash anomaly.

6 It had several advances. It goes us in
7 past dry out and it got us in past infiltration by
8 construction water. A lot of the surface or tunnel
9 wall samples had to be corrected.

10 The data had to be corrected for the
11 presence of construction water, and by going in four
12 meters and preserving the core, then we could also
13 extract water and conduct treading analyses.

14 One thing I have failed to include in this
15 history is that there was a peer review panel at the
16 Chlorine 36 dataset, and that peer review, one theme
17 that kept recurring is that you have got to go in and
18 try to do tritium.

19 So this was an opportunity also to do
20 tritium. Next slide, please. We were delayed at that
21 point, and there was a multi-month safety stand down.
22 I can't even remember what caused it now, but that
23 delayed things for several months.

24 There was a bit of a problem in getting
25 all the perceived QA procedures going at Livermore.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 Anyway, the holes were finally drilled, and we looked
2 only at the deeper two meters from the construction
3 water and dry out.

4 We sub-sampled or we sent samples for
5 Lawrence Liverman, and we took samples to Denver for
6 water analysis and tritium, and we sent samples to
7 AECL for uranium isotopes.

8 The Livermore -- the first Livermore
9 dataset was developed by an active leaching process,
10 with seven hours in a rotating tumbler; in contrast to
11 the previous Los Alamos methods, which was a passive
12 leach for 24 to 48 hours. Next slide.

13 The first Livermore results were presented
14 at the NWTRB Chair meeting in Pahrump, and the values
15 were lower than had been observed, and basically it
16 was concluded that that leaching technique was
17 probably too aggressive, and we were getting too large
18 a component of rock fluoride.

19 If the rocks are multiple reservoir
20 chloride, there would be chloride initially in the
21 volcanic rocks, and I think the average for the high
22 silica is something like 170 ppm chloride, and this is
23 primary chloride.

24 There would be chloride in the four
25 moderate in there would be chloride in fracture order,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 and presumably what you want to look at for finding
2 bomb pulse is to try to look at fracture water, which
3 you can't -- nobody has sampled fracture water, but
4 you can sample the salts. You can leach the salts.

5 So you try to balance the leaching to
6 maximize the meteor component, and minimize the rock
7 component. Anyway, next slide. So there was general
8 agreement that the dynamic leaching was a little too
9 aggressive, and there was an agreement among all
10 participants at that time that we needed really to
11 rest, have a sample to test the bleaching process.

12 And the USGS was charged with preparing
13 that sample, which we did. TRB too a very intense
14 interest in this, and wrote a letter to the OCRWM
15 Director urging a quick resolution, and that was on
16 June 16th of 2000. Unfortunately, we are still not
17 there.

18 We developed a path forward, and we got a
19 large sample from Niche-5 in the cross-drift. This
20 was crushed and sized in Denver, and aliquots were
21 sent to both Livermore and Los Alamos to conduct
22 leaching studies. Next, please.

23 These results were discussed at several
24 meetings, and there was a meeting in November of 2000
25 at the GSA meeting in Reno. Next slide. The bottom

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 line is that it was decided that the best way to go
2 about it was a passive leach, and to minimize the
3 time.

4 And at that time one hour was sort of
5 indicated as a desirable time for leaching of that
6 size of a fraction rock, even though that was in
7 somewhat of a contradiction with the earlier dataset,
8 where samples were leached from 24 to 48 hours. Next
9 slide, please.

10 So we needed to go back now and look at
11 the validation core again, and the approach this time
12 was we would crush the samples, and actually the
13 sample management facility crushed the samples, and
14 some of the remaining core, and this was done in
15 basically a brand new crusher.

16 The only thing that it had ever seen
17 before was other samples of the Topopah Spring type.
18 Samples were transported to Denver, and the USGS
19 leached the samples, and distributed aliquots of the
20 leach samples to Los Alamos and Lawrence Livermore,
21 both of which then spiked the samples with different
22 chloride isotopes, and prepared the silver fluoride
23 precipitates, and Lawrence Livermore ran the samples.

24 And generally the results were in fairly
25 good agreement between samples prepared at Los Alamos

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 and samples prepared at Livermore. The numbers ranged
2 from 200 times 10 to the minus 15, to 500 times 10 to
3 the minus 15, still lower than the previous Los Alamos
4 dataset.

5 At a meeting last January, we convened the
6 group in Denver, and we looked at the data, and there
7 was one dataset in the old Los Alamos data where core
8 from Niche-5 had been analyzed, or I'm sorry, Niche-1,
9 had been analyzed, and something like 8 out of the 10
10 samples that were analyzed revealed an elevated
11 chloride 16 value.

12 And so we thought, well, this is what we
13 need to do. First of all, we had a hard time finding
14 the core. It turned out that some of it was in the
15 USGS hydrological research facility, and most of that
16 had been used for physical property measurements, or
17 had been saturated with J-13 water, and so on and so
18 forth. But there was still a pretty good collection
19 at Los Alamos. So we split the core up. Next slide,
20 please.

21 And we agreed that we would do -- there
22 was concern that machine crushing might yield too much
23 fresh rock fractures, and therefore, overwhelm the
24 leachable chloride with rock chloride.

25 So we followed a procedure used at Los

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 Alamos, which was hand crushing on a steel plate and
2 a hammer. Los Alamos conducted their or analyzed
3 their six samples, and they reported ratios of 1140
4 times 10 to the minus 15, to 8580 times 10 to the
5 minus 15.

6 That is the highest or largest number that
7 has been reported so far. Chloride concentrations
8 were 1.3 to .67 milligrams per liter, and we processed
9 what should have been roughly an equivalent core in
10 Denver, and we got ratios between 244 and 708 times 10
11 to the minus 15.

12 Both groups had monitored leaching blanks
13 during that time and no leaching blanks were deemed to
14 be acceptable. So that is the most recent puzzlement
15 as to why these numbers differ.

16 CHAIRMAN HORNBERGER: Can I ask a question
17 on this, Zell? On the previous go around, the USGS
18 did the leaching and distributed the aliquots. Here
19 two different labs did the leaching.

20 Why did you do that apart from -- am I
21 reading this slide correctly, that leaching was done
22 both by USGS and Los Alamos? Whereas, previously it
23 was done just by USGS?

24 DR. PETTERMAN: That's correct, and it was
25 because of that, because previously it had shown that

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 if one lab leached a sample, and distributed the
2 liquid leaches, both labs could get the same answer.

3 So we were back to -- and we had already
4 demonstrated that to be true. So now we had another
5 chance, and the early Los Alamos data had said there
6 were elevated values, and so we just decided it was
7 best to let's just let those -- we didn't physically
8 split it. It was pretty rumblized, and so Bob Robeck
9 had inventoried what was available.

10 And we took alternate -- I don't know,
11 either one foot or six inch segments of rumblized
12 core, half to Denver and half to Los Alamos.

13 It should be, you know, unless fate is
14 really cruel, they should be comparable. The
15 statistics, the probability, of them being or leading
16 to these results is extremely low.

17 The bottom line though was that we got
18 different results, and again the leaching blanks were
19 okay at both laboratories. So we decided that one
20 thing that we did not have control on was the actual
21 crushing blanks.

22 So we got a hold of some computer chip
23 silicone from the DOE lab in Golden, the Energy lab,
24 and supposedly pure to six figures. And we crushed it
25 just like it were a rock, and using the same

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 equipment, and we also conducted a systems blank at
2 that time.

3 Unfortunately, our system blank, which
4 basically is pretending we have a rock and leaching
5 it, but there is no rock in the pan, our system blank
6 was a bit higher than what we had seen before, which
7 has confounded the issue.

8 But if we correct our crushing blanks for
9 that leaching blank, then our blanks, the crushing
10 blank, we have concluded is not a significant issue by
11 the USGS in Denver.

12 At the same time, Bob Robeck had surplus
13 material from one of the core samples, which he sent
14 to Denver, and we leached it, and we got essentially
15 the same number that he did, 1130 times 10 to the
16 minus 15.

17 So that we could confirm, and that is kind
18 of where we are at the moment. And I think that it is
19 very important, and that we have so much data now, and
20 so many efforts to try to resolve this issue, that let
21 me try to go through the conclusions here.

22 So this is kind of a summary. The old or
23 the early dataset at Los Alamos, samples from both ESF
24 and Niche-1, and this is the Sundance anomaly now, had
25 elevated Chlorine 36 values.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 The Los Alamos data on the Niche-1 core,
2 the most recent analyses, had elevated Chlorine 36
3 values. An early effort, and I think six samples of
4 the original Chlorine 36 validation core were analyzed
5 at Los Alamos from the Sundance.

6 Those did not have elevated values, but
7 the numbers were in the normal background range to the
8 Los Alamos dataset. Next slide.

9 The lowest values measured was that
10 original dataset at Los Alamos, or I'm sorry, at
11 Livermore, and the active leaching. And then next we
12 found no bomb pulse in the validation core holes, and
13 we found no bomb pulse in the Niche-1 samples. Next
14 slide.

15 So I think we are at a critical juncture
16 here, and it is extremely important that we have the
17 time to sensitize and integrate the existing data, and
18 after doing that, then come up with a path forward.

19 And to be honest, we just don't know what
20 that is at the moment, but we think that putting all
21 these data and having time to think about the data in
22 a report is a next very logical step.

23 The project has indicated that they could
24 bring one or more outside experts in to review the
25 report and whatever path forward we come up with.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 Let's go to one of the illustrations here, and maybe
2 that summarizes -- let's see, how about page 29.

3 These are all the data now plotted on the
4 -- the Y axis is one over chloride, and the reason we
5 do that is that in this ratio concentration space, if
6 you plot the reciprocal concentration, then binnery
7 mixing comes out as a straight line. That is the only
8 reason.

9 But the chloride concentrations is also
10 shown on the upper access. The triangles down in the
11 lower left-hand part are the Livermore results, and
12 the active leaching of the chloride validation core.

13 So that is one set of data. The solid
14 blue diamonds are the original Los Alamos dataset for
15 the Sundance Anomaly, and this is all Sundance
16 Anomaly. The orange triangles are the results, the
17 second round of results on the Chlorine 36 validation
18 core processed and leached in Denver, and analyzed at
19 Livermore, but aliquots also to Los Alamos, and spiked
20 at Los Alamos, and analyzed at Livermore.

21 And those are the interspersed green
22 triangles in that field of orange triangles. So there
23 is general agreement, and then the largest value is
24 that kind of open diamond, and represents the most
25 recent Los Alamos data on the Niche-1 core.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 And the little purplish triangles down
2 amongst the orange ones are the USGS results on the
3 Niche-1 core, both analyzed by Livermore. So again
4 that is kind of where we are, and I know that it is
5 not satisfying, and I think we have made progress.

6 I think we need three months now to
7 prepare the report, and I think we have to go into
8 what I would call kind of a forensic mode, and we have
9 got to really get into the old dataset, and really
10 look at it hard, and see if there is anything in there
11 that would be of interest in reconstructing how this
12 has evolved.

13 CHAIRMAN HORNBERGER: All right. Thank
14 you. Questions? Raymond.

15 VICE CHAIRMAN WYMER: It must be a little
16 disappointing to you that after all this time that we
17 still have something unresolved.

18 DR. PETERMAN: It is extremely
19 frustrating.

20 VICE CHAIRMAN WYMER: But there is a
21 suggestion at least that at least to the Sundance
22 Fault, that there is some evidence for fairly rapid
23 movement of water into the repository horizon, and
24 that is one part of the two-part equation, and how
25 fast does it move.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 But the second part is what volume moves,
2 because not much has moved, and you don't really care
3 with respect to the proposed repository. What do you
4 know, or what do you plan to know, or what does
5 somebody plan to know about the volume?

6 DR. PETERMAN: Well, I think that is more
7 of a modeling exercise and Los Alamos has addressed
8 that, and has concluded that the actual volume of
9 water is probably small.

10 Now, I see that there is a flaw in this
11 presentation. The dataset that I didn't mention was
12 the tritium data, which we have also done on these 50
13 core. And there again we have got another disconnect.

14
15 And in the Sundance Anomaly, we find no
16 tritium of any consequence. I mean, no tritium,
17 period. It is down to one tritium unit. In the south
18 ramp, where there is no elevated Chlorine 36 values,
19 we find significant tritium values.

20 So we have an anti-correlation between
21 tritium and Chlorine 36, even though the peer review
22 said that tritium is the ultimate hope for validating
23 the Chlorine 36.

24 But you can come up with post-hoc
25 explanations for tritium, and it is going to move into

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 the vapor phase, and Chlorine 36, probably not. So
2 you can come up with reasons why they might not agree

3 DR. GARRICK: How much cross-checking of
4 samples has there been in the analysis? Different
5 labs and even outside of the established --

6 DR. PETERMAN: I would refer that question
7 to Greg Nimz, who actually conducts the analysis. I'm
8 sorry, but I am not sure that I understand the
9 question. Are you asking how much cross-checking
10 within the samples that we have done in the last two
11 years under this validation, or cross-checking in
12 general between laboratories?

13 DR. GARRICK: Let's try and answer both of
14 them. Both sound interesting to me.

15 MR. NIMZ: Well, the best cross-checking
16 is probably the samples that were prepared at
17 Livermore Laboratory and at Los Alamos, and a little
18 more at the Livermore Laboratory, and we get very good
19 agreement as Zell pointed out in those.

20 Cross-checking around the world has not
21 been done except for sample response activity, where
22 one lab send this to the -- the same sample or a
23 similar sample, to two different laboratories for
24 purposes of turnaround time and that sort of thing.

25 And then in general analyses, the clean

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE, N.W.
WASHINGTON, D.C. 20005-3701

1 laboratories, especially I am familiar with the prime
2 laboratory in Indiana and Livermore. Those analyses
3 have generally compared very well.

4 DR. GARRICK: Have the results had any
5 impact on the models that are being used to analyze
6 radionuclide transport?

7 MR. NIMZ: I don't know the answer to
8 that.

9 DR. PETERMAN: Let me ask this question of
10 Abe Van Link, and of course, and he says no.

11 MR. VAN LINK: since we assume that this
12 data is correct, and it is fully incorporated into the
13 modeling, and until some definitive group comes in and
14 says that it isn't correct, we would not change the
15 model.

16 However, the very fact that we also have
17 some tritium in the south ramp shows that some very
18 small fraction as the model now indicates can move
19 rapidly. So probably the model wouldn't change anyway
20 even if this data came in. But it is a scientific
21 credibility issue for us.

22 DR. GARRICK: Thank you. Has there been
23 any indication of any gradance of this transport of
24 the chlorine, any particular location that has
25 indicated a more definitive flow pattern than maybe

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 you knew about before?

2 DR. PETERMAN: Well, the original dataset
3 has been used or explanations have been put forth on
4 that slide number six, which is the original Los
5 Alamos dataset.

6 Again, there are contradictions. The
7 south ramp, among the whole of the ESF, the south ramp
8 is the most broken up piece of rock. It is highly
9 pallid, and there are fractures there that when it was
10 drilled, it was breathing to the atmosphere and
11 blowing to the atmosphere.

12 And the contradiction there is that there
13 have been no bomb-pulse Chlorine 36 values found
14 there, but again there is tritium there, and so it is
15 still a set of contradictions.

16 And with those sorts of contradictions, I
17 guess I would be personally reluctant to say that I am
18 going to use these patterns to say too much about
19 specific flow paths or flow zones within ESF, because
20 there is still something that we don't understand.

21 CHAIRMAN HORNBERGER: Zell, let me try to
22 summarize what I take from your presentation. The
23 accelerator mass spectrometer appear to work. That
24 is, they give you the same answer if you give them
25 different aliquots.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 DR. PETERMAN: That's right.

2 CHAIRMAN HORNBERGER: You get, however,
3 different answers when different labs prepare or do
4 the crushing. So am I right in inferring that this
5 would either indicate that the USGS crushing adds an
6 anomalous amount of dead chlorine, or Los Alamos adds
7 an unusual amount of elevated Chlorine 36; is that a
8 fair assessment?

9 DR. PETERMAN: I think that is a fair
10 assessment. That's one thing that we tried to look at
11 by this crushing blank, which turned out to be
12 somewhat confounded by the fact that apparently a
13 leach wire suddenly was higher in chlorine than we
14 thought it was when we actually did the earlier
15 samples, or it was higher than when we did the earlier
16 samples.

17 So we have to make some assumptions about
18 calculating the crushing blank. If we use the leach
19 blank that was conducted at the same time as the
20 crushing blank, then we conclude that crushing doesn't
21 add anything significant.

22 But it is a complication that makes one
23 feel a bit uncomfortable still.

24 CHAIRMAN HORNBERGER: And I take your
25 point that you really need three months to reflect on

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 this and come forward with a plan, but in general
2 terms, do you anticipate that it might be reasonable
3 to plan to involve other groups, groups that have not
4 yet been involved in the process, in terms of trying
5 to resolve this?

6 DR. PETERMAN: I think the project is
7 considering that. I don't know if the DOE wants to
8 make a comment on that.

9 CHAIRMAN HORNBERGER: My question wasn't
10 what the project was considering. My question to you
11 as a geochemist is would that make sense?

12 DR. PETERMAN: Yes, I would welcome that,
13 personally welcome that, you know. Anything to get
14 this off of dead center.

15 CHAIRMAN HORNBERGER: Milt.

16 MR. LEVENSON: I have got a couple of
17 questions. In one of your backup slides, you identify
18 that the mechanical crushing equipment at Los Alamos
19 was found to be contained with chlorine 36.

20 Now, that contamination didn't originate
21 in the crusher. What are the chances of other things
22 in that laboratory are also contaminated? Has there
23 been a sort of forensic search of that laboratory to
24 make sure that it is a clean laboratory?

25 DR. PETERMAN: Bob Robeck, who has taken

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 over the Chlorine 36, actually works in a different
2 laboratory than that earlier work was conducted in.
3 The contaminated equipment was reported in that
4 earliest Chlorine 36 report.

5 It was detected and that's why basically
6 they went to the steel plate and hammer rather than
7 the mechanical crushing.

8 MR. LEVENSON: But contamination at the
9 level of 10 to the minus 15, some of my experience is
10 that something in a building is contaminated, and
11 everything in that building might well be contaminated
12 at that level.

13 And changing equipment, or even the lab
14 next door, doesn't necessarily help. The other
15 question that I had in connection with the anomalous
16 tritium, I have the impression, and like many
17 impressions, it could be wrong.

18 But I have the impression that some of the
19 drilling equipment that the DOE is using or has used
20 is recycled equipment from the testing station. Has
21 anybody looked seriously as to whether the tritium is
22 contamination brought in my drilling equipment?

23 DR. PETERMAN: Early on -- and this is
24 only sort of an antidotal recollection on my part, but
25 there was some contaminate drilling equipment used in

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 some of the surface-based drilling.

2 The drilling that was done underground, we
3 used brand new core barrels, and brand new bits, and
4 new core liners, in anticipation that we did not want
5 to have that possibility.

6 And the possibility that through the ESF,
7 through the Sundance, and drill hole wash anomaly, we
8 don't find any. And the same equipment was used in
9 the south ramp, and we sort of would say that
10 equipment is not a problem.

11 There was also in the lab, the survey lab,
12 there were early problems. The exit signs were
13 trituated, and so that created problems. And your
14 watch, if you have a trituated dial, you don't want
15 to be in there when you are extracting water. So,
16 yes, it is a tuff ball game.

17 MR. LEVENSON: Is the tritium
18 contamination in the south ramp been found in cores or
19 only in surface material?

20 DR. PETERMAN: The south ramp is water
21 extracted from dry bill core. Those are all by vacuum
22 distillation, and taking the preserved core, and
23 distilling it in a vacuum line.

24 CHAIRMAN HORNBERGER: Staff. Andy.

25 DR. CAMPBELL: Thanks. I have a lot of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 questions. Andy Campbell, ACNW staff. But I am going
2 to try to touch only a couple of them. Why is Iodine
3 129 not done? Is there a technical reason?

4 And the reason that I ask that is Chlorine
5 36 was produced in the '50s by bomb testing in the
6 Pacific, because of the irradiation and activation of
7 chlorine in the sea salt.

8 Tritium was actually mainly produced in
9 the tests in the atmosphere, in the hydrogen bomb
10 tests in the '60s after the breakdown of the test
11 data. The iodine, on the other hand, also has a
12 source from pre-processing in Sullyfield and the other
13 reprocessing plant in France.

14 And, of course, various programs around
15 the world have been putting out Iodine 29 for a long
16 period of time. So if you are seeing the penetration
17 of these isotopes to the repository, then Iodine 29
18 might be a good trace, that of more recent activity,
19 as compared to activity produced in the '50s and early
20 '60s.

21 That is a question I guess for you, and
22 then I will ask another.

23 DR. PETERMAN: That's interesting, as we
24 were just talking about that at lunchtime. When Mark
25 Haffey was doing the work at Livermore, he was moving

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 in that direction, and I don't really know how far he
2 really got. Drake would know. He took a position at
3 Purdue to oversee the AMS facility there.

4 And so basically we have not pursued.
5 Greg, do you want to say anything about 129?

6 MR. NIMZ: Yes, the only point I would
7 make is that it would be analytically very difficult,
8 really tuff right now with the amount of chloride that
9 we are getting from these samples.

10 And the amount of iodine is going to be
11 much less. So there is a very big question as to
12 whether we would even be able to analyze the iodine,
13 which would occur in concentrations of perhaps of a
14 factor of a hundred less than chloride.

15 So there is that analytical junk that we
16 would have to make, which would take several months of
17 preparation to just understand whether we could do
18 iodine with these very little concentrations when we
19 are doing this passive leachings.

20 DR. CAMPBELL: Okay. The next question or
21 questions has to do with the approaches used to
22 resolve contamination when you are doing trace
23 analyses.

24 This certainly is the first example of a
25 contamination issue, and the fact that virtually every

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 trace analysis of either an isotope or of a metal have
2 involved a number of years of kind of floundering
3 around until everybody agrees on a methodology, and
4 everybody agrees on an approach, and the way to do it,
5 and then people start getting consistent results.

6 Part of that process involves
7 systematically going through and identifying every
8 single possible source of contamination in every step
9 along the way. And it is not clear to me at least from
10 how these analyses have been done in terms of the
11 selection of samples, and not really analyzing the
12 same thing.

13 And it is not clear, for example, that a
14 reference material has been produced that has a known
15 concentration that each lab can include in a set of
16 samples to check on the validity of their analyses.

17 You typically do a check sample that is
18 very similar in matrix to the samples that you are
19 analyzing. Part of the problem, for example, is doing
20 distilled water and leech blanks, is that you don't
21 always get the same activities going on that you would
22 if you include a crushed sample and so on.

23 And there are all kinds of wrinkles on
24 this process, and it is very detailed, and it is very
25 obsessive for the analyst to do it, but it has to be

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 done to eventually ferret out if there is in fact a
2 contamination issue.

3 Is that all going to be what you guys have
4 done folded into this report so that an objective
5 outsider can say, ahha, have they looked at this area
6 and have they looked at that area.

7 And are there any further activities that
8 you plan to do to try and nail this down. The other
9 thing that people have done are inter-calibration
10 exercises, where they take the same sample, and
11 distribute it to half-a-dozen or a dozen labs to do
12 that analysis.

13 And let each lab work up that sample, and
14 then do a comparison, a blind comparison of the
15 results, to see if any particular lab either has
16 either or very low numbers, and could you comment on
17 that?

18 DR. PETERMAN: Well, I guess I would agree
19 with everything that you said there. It needs to be
20 done, and we have probably done some of it. I think
21 we will address those issues in the report, and it
22 will be part of our recommendations for a path
23 forward.

24 Part of it, you know, is always a resource
25 issue. You know, it is expensive analyses, and a

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 collection of samples that are less labor intensive,
2 and it doesn't take very long to burn up your budget.

3 And that is always an issue, but I agree
4 with everything that you said. I am certainly aware
5 of some of those historical problems in working at
6 that level.

7 We asked Greg at lunchtime how many folks
8 the world over have rocks that have chlorine 36, and
9 he said it is only you guys. I think there was an
10 additional comment there which I won't pass on.

11 So the point is that it is not something
12 that is routine, and we do need to think about
13 everything that you said.

14 DR. CAMPBELL: One last comment on the view
15 graph up there at the three different years worth of
16 data. The interpretation as I recall from the '97
17 report was that the high spikes that are categorized
18 as bomb-pulse above the maximum level were interpreted
19 to be bomb-pulse in association with fractures or
20 faults. There are a few exceptions, but mainly those
21 data are.

22 But below the maximum and above the lines,
23 there is a lot of scatter in the data until you get to
24 6,000. And then the data gets very tight. And there
25 were two explanations for that that I am aware of.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 One was that something happens at 6,000
2 that causes a flushing of the system, and the
3 scattering of the data before 6,000 might be
4 representing different amounts of pre-plisticing
5 (phonetic) water of different Chlorine 36 contents due
6 to changes in the magnetic field.

7 Bill Murphy at the Center did a
8 statistical analysis, and said, well, you could
9 explain all of that scatter below 6,000 as simply a
10 two-hand mixture of bomb-pulse contamination and
11 modern water pre-bombed modern water.

12 If that is the case, then it seems that
13 you actually have to nail this issue down even if the
14 model attempts to take into account fast paths,
15 because the one interpretation might be that that
16 scatter represents a lot more fast paths than just a
17 few fractions.

18 You could certainly reasonably interpret
19 that data in that way. This is real and not due to
20 contaminated samples, and then that would suggest that
21 its more important than just for a few fractures. It
22 might be important for a significant portion of the
23 rock.

24 DR. PETERMAN: Well, that's true, and also
25 that a similar lab arrived at a similar

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 interpretation, and that could explain all of that.
2 Most of it, except for the south ramp, and virtually
3 every sample, or most every sample there has a little
4 bit, variable proportions of bomb-pulse chlorine 36,
5 and reasonable interpretation.

6 MR. ROBECK: I am Bob Robeck from Los
7 Alamos, and I took over the project from June about
8 two years ago, and have been working and puzzled by
9 this issue ever since. It has been a frustrating
10 experience scientifically for me.

11 There has been a lot of talk -- well,
12 first of all, what you were saying over there, I
13 agree. Where the project is now, I think we have
14 eliminated a lot of first quarter issues that we have
15 been able to come up with through a considerable
16 amount of discussion and meetings.

17 And we said, well, let's get a reference
18 sample and try to develop a reference sample that we
19 can both work on. We tried that and we tried -- the
20 GS tried leaching and distributing (inaudible), and I
21 cross-sampled and sent them to Zell, and Zell has
22 cross-sampled.

23 And we are working through the first order
24 problems, and now we still don't have the answers, and
25 now we need to get to the difficult issues to address.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 And can we be missing something at the
2 very low level, or perhaps are we looking at more than
3 one problem rearing its ugly head, and from time to
4 time another problem perhaps rears its head at another
5 time.

6 Personally, I think that's where we are
7 right now, and I don't think we have a single issue,
8 and a lot has been said about the blank issue, and I
9 just wanted to address that.

10 When I took over the operation, it was
11 shortly after the fire at Los Alamos, and as a result
12 of the fire, I was no longer able to do the work the
13 laboratory that had been used previously by June. So
14 I relocated the entire operation about a mile way in
15 a completely different technical area, and a
16 completely different building.

17 I vigorously blanked that area, and the
18 blanks came up low, and that area is a non-rad area
19 within Los Alamos. I also modified the procedures so
20 that we could keep careful tabs of the blanks.

21 Through the course of the analyses now, I
22 have run some 100 samples and no fewer than about 15
23 percent of those are blanks. And every one of them
24 has come up quite low.

25 So that any contribution to Chlorine 36 by

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 the blank would not be significant, or would not
2 change any of the conclusions. The blanks that I have
3 taken do not include a crushing blank which is yet an
4 issue.

5 However, when we do a leach blank, we
6 allow that leach to sit out that length of the time
7 that we take to drive down our samples, which is
8 sometimes up to a week.

9 Whereas, we are crushing for approximately
10 an hour to maybe a few hours within that laboratory.
11 So I think any kind of fallout that we might get from
12 our crushing equipment, and I don't see where else it
13 could come from because the equipment is vigorously
14 cleaned.

15 So I think that we have done our best at
16 least to address the blank issue at this point, and
17 perhaps we need to take it a little further. But I
18 also wanted to say that the data that we have
19 generated do not in any way suggest that a random
20 blank is the problem here.

21 We are not seeing a random high ratio.
22 Rather, we are seeing ratios where they have been
23 determined in the past. So, for instance, he has
24 ditched one sample, and let me jump back.

25 Of the close to a hundred samples that I

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 have analyzed thus far, only one sample from the
2 cross-drip has what we would consider a bomb-pulse
3 value, which is just barely bomb-pulse value, between
4 1200 and 1300.

5 And then when we did this Niche-1 samples,
6 again processing them in the same way, most of them
7 did turn up to have bomb-pulse in the same area where
8 June located bomb-pulse, using modified methods in
9 different laboratories.

10 Likewise, I processed this Niche-1 samples
11 and did a couple of different experiments, and
12 separated them by size fractions, and you see
13 systematic differences within those size fractions.

14 And in this case the highest bomb-pulse
15 turned up in the finest fractions, but again the
16 systematics that we see from low ratios to high
17 ratios, and low chloride to high chloride for
18 corresponding samples do not smell like a blank
19 problem.

20 You would not expect those kinds of
21 systematics. I might also point out, too, June's
22 dataset, where most of these bomb-pulse values that
23 she did find are from her feeder base samples.

24 Whereas, within her systematic sample set,
25 I believe that only one sample has turned up bomb-

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 pulse. We are certainly concerned about the blank
2 issue, and I am doing what I can to address it
3 further, and we will continue to do that.

4 But right now I firmly believe that the
5 data does not suggest that a blank is an issue. I
6 don't know what the problem is and hopefully -- and I
7 think that our path forward, we really do need to step
8 back here and look at all of this data. For the last
9 two years, we have been working hard to generate a lot
10 of data, and I don't think we have given the dataset
11 justice at this point. So that is our goal for the
12 next two months here.

13 DR. RYAN: I am looking at the figure on
14 page 6 and I have been thinking here quietly about
15 statistics. And as the ratio gets bigger, that means
16 that there is more Chlorine 36, right? Yet the
17 uncertainty gets bigger as well.

18 I would think it would be just the other
19 way around in bars that are shown on this graph, and
20 I don't have the data, and so obviously I am shooting
21 in the dark here.

22 But as the amount of Chlorine 36 gets
23 smaller, and smaller, I would think the uncertainty
24 and your knowledge of its value gets bigger. I mean,
25 that is just simple sampling statistics to my way of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 thinking.

2 But yet it is just the opposite on this
3 graph. So I am stuck with the basic statistics
4 question, and that is when you measure Chlorine 36 and
5 say it is this value, I am stuck with how well you
6 know that. So I am trying to figure out if I should
7 interpret things that are below these various
8 horizontal lines as being different or not different.

9 And I am kind of stuck with the statistics
10 that you used. I know that this is not a radiometric
11 measure. So it is a different kind of uncertainly
12 analysis perhaps. But I don't really have a feel for
13 how accurate any given measure is.

14 And I know that you can't do it because
15 you would run out of sample, but if I measured the
16 same sample 50 times, what would the average be and
17 what would the standard deviation be?

18 What I am reaching for is concepts that we
19 use in radiometric analysis of minimum detectable
20 activity, critical level, and things like that which
21 we can do hypothesis testing.

22 I mean, you have not talked about that
23 here, and I don't know if you have done that, and I
24 apologize if you haven't. I have not seen it yet.
25 But that kind of thinking may be helpful perhaps. I

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

1 don't know.

2 DR. PETERMAN: Yes, it is helpful.
3 Attempts to replicate analyses on individual samples,
4 and June reports this in her reports, has not worked
5 very well. Both data are available.

6 And so - well, Leonid, do you want to
7 comment on these uncertainties? This is Leonid
8 Neymark.

9 MR. NEYMARK: Just that we started with
10 the largest uncertainties, for example, for Chlorine
11 36 and there is a reason for that. But in most cases,
12 and in June's data, a bomb-pulse signal was obtained
13 for a sample with lower total chloride concentration,
14 and it increases the total there in that one.

15 DR. RYAN: That doesn't help me very much
16 though. The more chlorine 36 you have in the sample,
17 you would think that if the measurement quality
18 increases with chlorine 36 concentration that's not
19 true?

20 MR. NEYMARK: No, it is not. A higher
21 chlorine 36 total chloride ratio doesn't mean that you
22 have more chloride 36 in your sample. It depends on
23 the total chloride concentration. So if those low
24 chloride samples, you have a higher ratio larger.

25 DR. RYAN: I guess I would like to follow

1 up if I could. That may not be a meaningful error to
2 report then, because are you measuring the ratio or
3 are you measuring the chlorine 36?

4 MR. NEYMARK: I think it is that if you
5 have less chloride -- generally speaking, if you have
6 less sample to analyze, your accounting statistics is
7 -- you know, you get less counts and therefore your
8 error is larger, regardless of the ratio of chlorine
9 36 to total fluoride.

10 The total amount of chlorine 36 are lower
11 because you have lower chloride sample. Is that true?

12 MR. TYNAN: Let me first say that I know
13 very little about the data on page 6, because this was
14 not done by me. It was done by the laboratories, and
15 so I am not sure what the meaning of the error is on
16 here. But to answer your question, in general, and to
17 follow up on what Leonid was saying, is that this is
18 simply an accounting statistic problem.

19 If you have a hundred counts of Chlorine
20 36, you have 10 percent data. And so if you have or
21 if you are running samples, and if the laboratory
22 chooses to run the samples for five minutes, the
23 samples with more Chlorine 36 will have more counts,
24 and therefore, better accounting statistics.

25 DR. RYAN: I guess I am getting in a very

1 fundamental question of the accuracy and precision of
2 the measurement relative to minimum detectable levels.

3 And without some understanding of minimum
4 detectable levels relative to measured levels, it is
5 very difficult to either ascribe or take away meaning
6 from the results.

7 And I assume that just based on what you
8 talked about that we are at very, very low levels to
9 begin with, and I am just going to try to assess some
10 statistical significance to that, and I have not seen
11 information that helps me to do that yet.

12 MR. TYNAN: Again, I don't know about the
13 data on this sheet.

14 DR. RYAN: I appreciate that.

15 DR. GARRICK: One of the questions that
16 this committee often asks is so what with respect to
17 bottom line health and safety issues. I suspect that
18 you have done enough work now on these ratios on
19 chlorine to be able to categorize what the outcome is
20 probably going to be, in terms of it being one or two,
21 or three different scenarios.

22 In other words, you probably have a pretty
23 good handle on what is going to be the outcome of your
24 path forward if you had the option of identifying two
25 or three possible outcomes.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

WASHINGTON, D C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 Given that, and this is probably a
2 question for DOE, and not to you, but what is the
3 implication? Has somebody considered what the
4 implication might be to the project and to the
5 analysis?

6 Abe Van Link has already said that the
7 assumptions have sort of embodied in reference to what
8 we were talking about earlier, the possible inability
9 to get any advantage from these measurements.

10 But I am curious as to whether or not this
11 is really going to have much meaning in terms of the
12 project and in terms of the performance assessment.
13 Abe, this is probably a question for you.

14 MR. VAN LINK: Abe Van Link, DOE. As I
15 have already mentioned, we fully incorporate the
16 information from the Los Alamos work into our
17 performance assessment at this point.

18 I think where this comes down now is we
19 need to push to a resolution, because we have several
20 august organizations that we rely on for scientific
21 information, who have come to a point where their own
22 scientific credibility is on the line.

23 So we need to push forward to a resolution
24 because from my perspective it is in our best
25 interests that we get to the bottom of this, and are

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 able to establish or reestablish credibility for these
2 institutions.

3 Now, if some contamination is found
4 somewhere, so be it. If they find a new mechanism
5 that one organization was not aware of, so be it.
6 Those are the two or three scenarios that we can come
7 up with.

8 But either way a resolution will bring us
9 reestablished credibility. It is not something that
10 we want to shove under the rug and say, well, it
11 doesn't matter to performance anyway. We want to get
12 to the bottom of it.

13 DR. GARRICK: What about if it comes up
14 that there is no bomb-pulse or no evidence of it? Is
15 that going to change anything?

16 MR. VAN LINK: I hate to speculate on
17 that, because as I said, we do have the tritium work
18 on the south ramp that shows that there are fast paths
19 other than the Chlorine 36 paths, and we do have one
20 tritium sample, I believe, that is associated with a
21 fault in Alco 6 or 7.

22 DR. PETERMAN: Yes.

23 MR. VAN LINK: So on the other hand, it
24 probably would change our qualitative understanding of
25 the unsaturated zone. You know, we do have -- most of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 the water there is pristine water still, and we do
2 have very good evidence from Zell's work that if you
3 look at the bulk of the rock, it doesn't see water
4 very often.

5 It sees it maybe during an ice age, and so
6 this is still consistent with our current model
7 though, that we have very little water moving through
8 fast paths, and the bulk of the water is resident in
9 the rock for extremely long times.

10 I think that Mark Tynan was going to say
11 something.

12 MR. TYNAN: Yes, Mark Tynan, DOE. You
13 covered one of the points already, but the second
14 point that I would make is that if our path forward
15 isn't defined until January, let's say, or the reports
16 aren't out, our ability to resolve this prior to the
17 license application is not a high percentage of
18 success.

19 So it is likely that this is the ongoing
20 work and post-LA submittal in December of '04.

21 DR. GARRICK: Thank you.

22 MR. COBEST: Tim Cobest, ACNW staff. I
23 assume that this is all being done under DOE's quality
24 assurance program, have you had an audit done or
25 anything?

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 Have you had them come in and give you an
2 independent look at it and come up with anything as
3 far as procedures, and as far as how you clean your
4 test equipment that you were talking about?

5 You know, handling samples, and have they
6 come up with anything or have they looked at it?

7 MR. TYNAN: Livermore just had an audit,
8 and -

9 MR. COBEST: And did they look at this
10 issue?

11 MR. TYNAN: Yes, and we have I think
12 audits at least once a year.

13 MR. ROBECK: We certainly have audits of
14 our scientific notebooks and our procedures, and those
15 are ongoing. As far as having and testing equipment,
16 it comes and is examine, but as far as someone
17 actually coming in and observing a procedure that
18 doesn't happen.

19 MR. LEVENSON: The conversation has been
20 focused on Sundance, but in the original samples, and
21 in fact the highest Chlorine 36 ratio was not at
22 Sundance, was a 2,000 meter and five separate samples
23 indicating bomb-debris. Is 2,000 meters still part of
24 the Sundance?

25 DR. PETERMAN: It is part of the drill

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 hole life structure, and that was in our initial plan.
2 We allocated 40 of the bore hills to the Sundance and
3 10 to the drill hole wash.

4 MR. LEVENSON: And I gather that there
5 have been some more recent samples that confirm the
6 early Sundances, and has there been any recent samples
7 concerning the early high ones of 2,000 meters,
8 especially since the very highest ones were there?

9 DR. PETERMAN: Not that I am aware, no,
10 according to the reports. The report data, that is
11 the original data, or the early data.

12 CHAIRMAN HORNBERGER: I just wanted to
13 make sure that we are clear on this now. Milt said
14 that from your 40 samples that you have confirmed high
15 chlorine-36 ratios at the Sundance? That wasn't my
16 understanding.

17 DR. PETERMAN: No, we haven't. Not in the
18 validation core, we have not.

19 CHAIRMAN HORNBERGER: I just wanted to
20 make sure that we are clear on that. That the
21 disagreement was the Niche-1 samples; is that right?

22 DR. CAMPBELL: One last comment here is
23 Mike Ryan's observation of the statistics. Has
24 anybody done an analysis of the statistics of these
25 high chlorine-36, but low chloride samples that are

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 heavily in the bomb-pulse area?

2 And that is a very curious result to me,
3 and is there an explanation for that? If you look at
4 everything about the 1250 line, most of those samples
5 have much higher air bars, which if I understand the
6 argument about accounting statistics, it is because
7 they have overall very low chloride, and that seems to
8 be a curious result, and possibly an explanation
9 buried in it.

10 So have you guys pursed that or do you
11 intend to pursue that?

12 DR. PETERMAN: I guess I am a little dense
13 here. I am not sure that I understand. Does anyone
14 want to -- Leonid, do you want to --

15 DR. CAMPBELL: The air bars at everything
16 about 1250 on the graph on page 6, the original
17 dataset, that all of the high fluoride Chloride 36
18 samples appear to have significantly larger air bars
19 associated with them than the stuff below your cut-off
20 point.

21 And that is a curious result. That is not
22 what I would expect for a natural system, unless you
23 have some sort of explanation for why those samples
24 have a low overall chloride.

25 I understand the accounting statistics

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 argument, but from just a phenomenological point, why
2 would the high point 36 samples almost uniformly have
3 relatively low amounts of chloride?

4 DR. PETERMAN: Now, one could speculate.
5 Perhaps it is a function of -- well, there are a
6 number of factors, such as grain size, and how
7 rubblized the sample might be, and leach time, and all
8 of that.

9 If you look at the slide on page 28, it
10 sort of shows the same thing, and again that is the
11 low concentration values. I mean, this is the
12 validation core, and that doesn't fit the trend that
13 you were talking about in the early Los Alamos data.
14 The lowest concentration values are all less than five
15 or six hundred.

16 DR. RYAN: And that point is highly
17 uncertain, and that is a whole different
18 interpretation than if it has got a very small error.
19 So uncertainty analysis has got to be factored in to
20 help with the interpretation I think.

21 DR. PETERMAN: In addition to analytical
22 uncertainty.

23 MR. ROBECK: I am not too terribly
24 familiar with the issue of the error bars there, but
25 what I am familiar with is the data in the cross-

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 drift. We don't see a good correlation between
2 fluoride concentration and Chloride 36 ratios, at
3 least in the samples with bomb-pulse.

4 So we don't necessarily see that the
5 highest Chlorine 36 samples have the lowest chloride.
6 They are kind of just scattered all throughout typical
7 chloride ranges.

8 DR. RYAN: Now, on distribution to
9 understand in detail, because if you can understand
10 that in detail, you can assess some uncertainty on
11 that basis. And if you don't understand that
12 distribution, or have not figured it out from your
13 data yet, that is something that has to be done.

14 MR. ROBECK: Agreed. I am looking at the
15 dataset from June, and I am puzzled by the reason for
16 those larger air bars with the higher Chlorine 36
17 values. One thing that comes to mind, and I just
18 throw this out, as I don't know it is in fact the
19 reason here.

20 But when I do an analysis, I have
21 uncertainty based on internal accounting statistics.
22 I also have an uncertainty that I will assign based on
23 external reproducibility.

24 Now, that would generally be a percentage.
25 Now, if that is what June has done here, and simply

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 assigned a five percent uncertainty for
2 reproducibility, that those will appear as larger
3 error bars.

4 DR. RYAN: Again, the basis for that
5 assignment is critical. If it is just a typical
6 measure error is five percent, that's not going to get
7 it.

8 MR. ROBECK: That would be your internal
9 error based on accounting statistics. It would be
10 based on external reproducibility of standards.

11 DR. RYAN: You know, I guess my general
12 reaction to the discussion is without a systematic
13 development of uncertainty analysis in the
14 measurements, and all the components, whether it is
15 instrument uncertainty, sampling uncertainty,
16 contaminant uncertainty, and all those things, you
17 really can't interpret these measurements as
18 effectively as you could with the uncertainty.

19 You know, simple examples like it took a
20 hundred samples of blanks and what is the average
21 measurement. Theoretically, they should all be the
22 same. Well, if they are not, what is the standard
23 deviation.

24 I mean, something as simple as that gives
25 meaning to how you sample, and 67 percent of the time,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 you will be within that. I mean, everybody knows
2 those statistics.

3 And in fact without that laid out on top
4 of an interpretation, it is hard to ascribe meaning to
5 it.

6 MR. ROBECK: We have analyzed standards,
7 and along with each set of samples, I will send a few
8 standards, which I know the ratio -- and it is a
9 certified ratio, and those ratios come in very good.

10 DR. RYAN: That is the part that is not
11 going to come out (off microphone).

12 MR. ROBECK: Right. And let's just not
13 report it here, but it is reported, or at least it
14 will be reported. But, yes, along with blanks that I
15 typically submit, I submit 10 percent of my samples
16 will be standards, and some of them will be spiked
17 standards, and some of them will be unspiked
18 standards, and those results come out quite good.

19 So the results are reproducible, at least
20 when we have a nice homogeneous sample, and therein
21 lies the problem. It is hard to envision getting a
22 rock that we could claim is homogeneous that we could
23 process 30 times, and then do statistics on our
24 numbers.

25 DR. RYAN: Again, that is not what the

1 blanks, and dupes, and all of that are addressed at --
2 is a fundamental sampling error that -- you know, I
3 think that relates to the steel plate issue, and some
4 of the other things that you have mentioned.

5 But again quantifying that systematically
6 is critical. If you have not done that failure repeat
7 sample, you should.

8 DR. PETERMAN: In terms of the samples,
9 there is really attempts to replicate. You know, it
10 was very difficult to replicate results. So if you
11 were to use those duplicates, in a statistical sense
12 the error bars from those would be off the chart.

13 MR. ROBECK: And that is exactly what we
14 are talking about, and I think that has been the
15 thrust of the early part of this project. We have
16 been exchanging samples, and we did try to prepare
17 what we thought would be a good reference sample, the
18 Evalve-1 sample, and we performed a number of analyses
19 on that.

20 And lo and behold, it wasn't homogeneous.
21 It is not a straightforward problem to really say,
22 well, here is a homogeneous rock and analyze it 30
23 times.

24 CHAIRMAN HORNBERGER: I think the bottom
25 line is that it is a fairly easy problem if your

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 sample or your analysis cost is \$10 a sample. And I
2 think that you are probably not doing exactly what
3 Mike wants because your costs are just a little more.

4 MR. ROBECK: It would be about 40 or 50
5 samples a year.

6 DR. RYAN: I appreciate the difficulty
7 (off-microphone).

8 CHAIRMAN HORNBERGER: Thanks very much.
9 That was very informative, Zell, and we look forward
10 to hearing about your pass forward, and I do think
11 that I really appreciate Abe's answer, because I do
12 think that it is -- well, I would express my belief
13 that it is critical that we do get to the bottom of
14 this.

15 We don't want to look at this as a
16 puzzling question mark just sitting out there, and I
17 think we can do it. And I think we will come up with
18 a good plan. Thanks very much. We are going to take
19 a break now, and let's take a 25 minute break.

20 (Whereupon, at 3:18 p.m., the meeting was
21 recessed, and the meeting was resumed at 3:48 p.m.)

22 CHAIRMAN HORNBERGER: Okay. I would ask
23 everyone to make sure that they have signed in. We
24 would like to keep a record of who attend our meeting.

25 We are going to continue our presentations

1 on the DOE scientific update, and we are going to hear
2 some of the results on microbial-induced corrosion,
3 and we have a presentation from Joanne Horn. Joanne.

4 DR. HORN: I just wanted to first thank
5 the committee for giving me the opportunity to present
6 an overview of our program on assessing the impact of
7 microorganisms on long term nuclear waste containment.
8 I think we are ready for the first slide.

9 Thanks. Mostly our program has been
10 focused on the effects of microorganisms on the waste
11 package, and these are basically categorized as
12 microbiologically influenced corrosion or MIC.

13 This is really a complex set of
14 interacting microbial facilitated processes, and it
15 includes acid production by bacteria, as well as iron
16 oxidation and reducing reactions, sulfate generation,
17 with a reduction of sulfate, and hydrogen production.

18 And also the brown kind of bubble there
19 represents what we call biofilm. All these bacteria
20 are embedded in a matrix of polysaccharide, but it is
21 also generated by bacteria.

22 And the polysaccharide are long chain
23 sugars that produce a kind of slime. The slime
24 prevents the diffusion of oxygen towards the metal
25 surface, and that also produces conditions that can

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE, N.W.
WASHINGTON, D.C 20005-3701

(202) 234-4433

www.nealrgross.com

1 accelerate corrosion.

2 Now, which of these reactions occur is
3 really dependent on a number of variables, including
4 the environment. That is, for example, that you can't
5 get sulfide generation without having sulfate present,
6 for example.

7 Also, the organisms that are present and
8 the material under consideration. Next slide, please.
9 So the goals of this program then are to determine the
10 potential for MIC in the Yucca Mountain repository,
11 and determine the conditions under which MIC would
12 occur, and that includes the boundary conditions for
13 microbial growth since we expected initially will
14 start with a sterile environment, at least on the
15 waste package because of the radiation fields
16 generated by the decay of the waste.

17 But that eventually we did either a
18 reintroduction of bacteria or a regrowth of those
19 organisms that could survive through that radiation
20 field.

21 Also, the conditions for microbial
22 activities, and so again that would be -- you know,
23 you have to have the necessary sulfates for a given
24 end-product to be generated.

25 And also the quantified rates of MIC on

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 the waste package materials, and that would include
2 the production of dilatory and metabolic end products,
3 and also the direct effects on candidate waste package
4 materials. Next slide, please.

5 Okay. So we have taken this kind of
6 multi-prong approach to answering these questions, and
7 among them ethological studies, and we are looking at
8 the types of organisms that are present, and expected,
9 and that would essentially establish the potential for
10 MIC.

11 The conditions under which microbial
12 growth would occur, and if you couple that with some
13 of the thermal hydrological testing, for example, you
14 could estimate the time that the MIC might initiate,
15 and that will become clearer on later slides we think.

16 Looking at the effects of microbial
17 activity on water composition, and so that would be a
18 kind of indirect effect of bacteria or fungi. For
19 example, if they were to acidify the ground water, and
20 then the ground water impacted the waste package.

21 We need more traditional electrochemical
22 studies to quantify the overall changes and corrosion
23 rates due to MIC, and these studies can also indicate
24 the mechanism by which this acceleration occurs.

25 We are performing accelerated testing as

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 well, using both mixed cultures, and that is the
2 entire Yucca Mountain community, as well as using pure
3 cultures with defined microbial activities.

4 And in these studies we are looking at the
5 survecial effects of the materials, and the
6 biochemical effects on water chemistry, and the pure
7 culture studies can provide boundary conditions, and
8 for example, the generation of these deleterious end
9 products. Next slide.

10 Okay. So first I would just like to just
11 address the ecological studies and we are doing a
12 characterization of the Yucca Mountain microbial and
13 fungi communities, using a number of different
14 methods, and we have also determined what the extant
15 microbial densities in the mountain are, and the
16 growth limiting factors. Next slide, please.

17 Okay. We started these studies a number
18 of years ago by simply isolating microorganisms from
19 rock that was excavated aseptically from the mountain.
20 This is within the ESF.

21 And also from the large file test, and
22 what you are seeing on the left there -- and I don't
23 have a pointer, and so I'm sorry. Oh, do we have a
24 pointer in the audience? Wonderful. My hero.

25 Perfect. So what you said, hopefully it

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS

1323 RHODE ISLAND AVE., N.W.

WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 won't blind you in the process. On the left, you will
2 see -- or laser paint you. Okay. Those are little
3 bits of rock that we actually collected from the
4 repository, aseptically crushed them and aseptically,
5 and what you see there are bacterial colonies growing
6 right out of that.

7 And those are criteria that are contained
8 on the surface of the rock, and each one of those
9 colonies rises presumably from a single cell. On the
10 left, again, you see bacterial colonies, and those are
11 from actually artificial poured water formulation that
12 we washed this rock with, and then plated that out,
13 and these are all on low nutrient media.

14 And so you can see that there are indeed
15 bacteria that are contained within the mountain. Next
16 slide, please.

17 Okay. What we did initially was to first
18 isolate these bacteria, and speciate them, and then we
19 tested them for a number of activities that were
20 associated with corrosion, and found that indeed many
21 of these had these activities.

22 And so were thereby established the
23 potential for MIC to occur. Next slide, please. We
24 also determined what the bacterial densities in the
25 mountain are, and we did this not by using growth, but

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 by directly extracting fossil lipid fatty acids, which
2 are membrane components, directly from a rock core.

3 What we did was that we drilled the rock
4 core out of the ESF, and split it in two, and one
5 representing the sort of region that was closest to
6 the drip wall, and one that was further into the wall,
7 and we found that there was some difference in fossil
8 lipid content.

9 You can estimate the number of bacteria
10 here by normalizing the extracted fossil lipid to that
11 from a known number of bacteria, and you can see that
12 there was some difference between the surface and the
13 at-depth cores.

14 But the bottom line was that it was about
15 10 to the 4th, or 10 to the 5th bacteria per gram of
16 dry rock. The next slide.

17 Okay. We have also done a number of
18 growth studies. This is a graph, and we are looking
19 now just at crushed rock from the site, and amended
20 with -- this is assimilated ground water at 1-X
21 concentration, with or without glucose.

22 And looking at the growth of bacteria from
23 the rock over time, and what you see is that as soon
24 as you add ground water, you get a significant
25 increase in the numbers of bacteria that you can

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

1 recover in the acetous phase, up to or from 10 to the
2 6th bacteria, and approximately without glucose added,
3 or up to 10 to the 8th with glucose.

4 So this showed us that the major limiting
5 factor to growth was water availability. And as soon
6 as you add water, you are going to get a significant
7 amount of bacterial growth.

8 And we have also done other studies that
9 I didn't think I would have time to show here, and so
10 I just mention them here. We have also established
11 that phosphate is the major nutrient limiting factor
12 in the mountain, and that if you actually add
13 phosphate back to these systems, you get an increase
14 on the order of one to two orders of magnitude.
15 And carbon is well as this slide shows.

16 There is apparently enough sulfate and
17 nitrate in the mountain to support growth, even in 1-X
18 ground water. Next slide, please. Now, this is
19 important because it tells us when the possible kind
20 of on-switch for bacterial effects would occur during
21 a repository revolution.

22 And I just want to apologize here for the
23 slide. I think we lost a little in the transport of
24 these slides from Livermore to here, but on the left
25 is relative humidity, and this is actually down from

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 Tom Bucheff's modeling group at Livermore, the thermal
2 hydrology.

3 And what we are looking at is the relative
4 humidity on the rock walls over time after closure.
5 Okay. So this would be after ventilation is shut off,
6 and what we see here is that in areas of low
7 infiltration, the dose of humidity never increase over
8 70 percent.

9 But in areas of higher infiltration and I
10 think that is about 50 millimeters per year, you
11 almost maintain a hundred percent humidity on the rock
12 walls.

13 So knowing that water is a major limiting
14 factor for growth, we could see that in areas of high
15 infiltration, you will have growth supported almost
16 immediately after closure.

17 Whereas, in areas of low infiltration, you
18 may never reach the humidity's that are required for
19 growth, and actually in the models we have put the
20 cut-off for bacterial growth at 90 percent humidity,
21 which is probably conservative.

22 The literature is more on the order of 95
23 percent. Okay. Next slide.

24 CHAIRMAN HORNBERGER: Joanne, can I --

25 DR. HORN: Sure.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 CHAIRMAN HORNBERGER: Going back to your
2 previous slide, where you concluded that water is the
3 major limiting factor, what are they growing on? I
4 assume that these are aerobic experiments?

5 DR. HORN: Yes. These are aerobic
6 experiments.

7 CHAIRMAN HORNBERGER: And what is the
8 energy source?

9 DR. HORN: You know, we -- I don't know
10 whether it is dead cells, and if you look in the
11 literature, there is some evidence in the deed
12 subsurface, things like organic carbon being a
13 possible source.

14 Some of these organisms do fix CO₂, and so
15 not all of them need an organic carbon source. You
16 know, we have isolated all the bacteria that we could
17 out of those experiments, and indeed we have found
18 some CO₂ fixers.

19 MS. TREICHEL: What is the numbers on the
20 bottom?

21 DR. HORN: Maybe we should -- oh, I'm
22 sorry, on this slide?

23 MS. TREICHEL: Yes.

24 DR. HORN: I think it starts at 150 years,
25 because I think that's when closure starts. And I

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 think those are a hundred year increments.

2 MS. TREICHEL: And 450 and -

3 DR. HORN: Right.

4 MR. LEVENSON: Joanne, on your slide that
5 George just asked about, where you have the sterile
6 control. What was the water and glucose, or what was
7 the sterile control with water, and with glucose, or
8 without glucose?

9 DR. HORN: The sterile control actually
10 simply contains rock that was sterilized. What we do
11 to sterilize the rock is that it is actually fairly
12 typical to sterile Yucca Mountain rock.

13 We have tried autoclave emitter
14 periodically and that doesn't work. We use a gamma or
15 a cobalt-60 source, and we eradiate it for about at
16 least three mega-reds.

17 MR. LEVENSON: And what was the media?
18 Was it in water or in --

19 DR. HORN: Yes. It was, and so you then
20 have to sterilize rock or non-sterilize rock, and we
21 added a formulation that approximated Delaney's
22 formulation for J-13.

23 I can show you that. I actually brought
24 some extra overheads. You know, I apologize, because
25 I thought that I would have a little less time than I

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 did. So I kind of eliminated some things. But if you
2 are interested -- well, okay, next slide please.

3 Okay. When you grow organisms from any
4 environmental sample for that matter, you only recover
5 about one percent of those organisms that are present.
6 So to overcome that, there has been methods developed
7 to directly extracting DNA from environmental
8 materials, and they characterize in the organisms by
9 sequencing the DNA that has been extracted.

10 And we have actually done a study on Yucca
11 Mountain rock, so that we kind of like brought out a
12 stone, and we got DNA out of rock. It took about half
13 a kilo of rock to extract a sufficient amount, but we
14 were able through various biochemical and genetic
15 manipulations to separate these DNAs, and to take the
16 unique ones, and have them sequenced.

17 And what this is, is to follow the genetic
18 or evolutionary tree of the organisms that we were
19 able to identify, using this DNA analysis. And we
20 recovered about -- well, we identified about 65
21 different organisms.

22 And you can see that they stand out --
23 these are actually about 45 of them, and we have 20 of
24 them that we still need to actually insert into the
25 tree.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

1 And then you can see that they span over
2 a broad and follow a genetic range, and they include
3 these high GC gram-positive organisms that are
4 typically found in betas one areas, and they are very
5 resistant to desiccation, and a number of other
6 organisms.

7 These proteobacteria are very
8 metabolically diverse, and a lot of them produce
9 acids, and have different metabolisms that are in fact
10 associated with corrosion.

11 So this is really meant to give us a kind
12 of baseline, although the repository is expected to be
13 an open system and so anything that we presume is
14 going to be able to invade and get in there. But at
15 least we will know what we are starting off with.

16 And if we associate the metabolic
17 activities with their ability to produce corrosion of
18 these various groups of bacteria, we may be able to
19 get a handle on at least what we will be dealing with.
20 Next slide, please.

21 We also looked at or identified a number
22 of different fungi and we have identified these.
23 These were actually obtained by slotting and just
24 growing and isolating various bacteria from a region
25 of the ESF where there ventilation had been shut off.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 And so fungi are important or potentially
2 important because they produce organic acids, and the
3 waste package materials could be susceptible to these
4 production of bioorganic acids. Next slide, please.

5 We also have done some experiments or we
6 are actually in the process of doing these now, but we
7 have a long-term corrosion experiment that is going on
8 at Livermore, and this is depicted here. This is a
9 picture of the facility.

10 Each one of these tanks is about a
11 thousand liters and they contain -- they are actually
12 environments that mimic the expected repository
13 environment over time.

14 They vary in ionic strength, and
15 temperature, and pH, and although no bacteria was
16 introduced intentionally into these tanks initially,
17 we had preliminary evidence that at least some of the
18 tanks had been at least somewhat colonized.

19 But what is interesting to us about this
20 is that it sort of reflects the repository evolution.
21 That is, that you start off with a fairly sterile
22 environment, and then kind of anything that is wrong
23 that can survive in there will do so.

24 And so we thought that it would be a good
25 thing to test these tanks and analogously determine

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 what the microbial sort of roster of organisms is in
2 there to see what may fly into the repository and
3 survive.

4 Okay. Next slide. So this is the results
5 from one of these tanks. This is a tank that contains
6 water that is meant to mimic dilute ground water at 60
7 degrees, and it contains the corrosion resistant
8 materials like Alloy-22.

9 And we found five different groups of
10 organisms I should say, and we actually had an
11 organism that is radiation resistant interestingly
12 enough, and we also found one that was heat tolerant,
13 and then the bacilli, there were five different
14 bacilli that we isolated that were identified that
15 were actually all sporulating organisms that came in
16 with both desiccation and high temperature.

17 And we are analyzing another tank now that
18 is acidified water at 60 degrees, and from that we
19 have observed a very strong DNA signal, and we have
20 cloned, or amplified and cloned the DNA, and we are
21 screening them now to determine which organisms are
22 present.

23 MR. LEVENSON: Joanne, excuse me, but on
24 your slide that shows the facility, does the tank
25 environments mimic expected repository environments?

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 These tanks all have liquid phases?

2 DR. HORN: They both -- actually they are
3 half full, and so they have half of the samples of the
4 corrosion coupons are actually submerged and then half
5 of them are in the vapor phase.

6 MR. LEVENSON: It may be that a possible
7 repository environment would be better than expected.
8 It is full of water.

9 DR. HORN: Right. This is true. I guess
10 mostly the chemistry was what we were most concerned
11 about when devising the environment that was being
12 tested. But thanks, Milt, you're right. Next slide.

13 So just a summary then of some of these
14 ecological growth studies. We know that
15 microorganisms are extant in Yucca Mountain rock, to
16 the density of about 10 to the 4th, to 10 to the 5th
17 bacteria per gram.

18 There is also a wide variety of fungi, and
19 the major growth limiting factor appears to be water,
20 and when water becomes available, we will expect that
21 microbial growth will ensue.

22 That also we are expecting that
23 infiltrating water will likely transport organisms
24 into the repository, and cultured Yucca Mountain
25 bacteria have activities associated with MIC, and this

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 establishes a potential for MIC in the repository.

2 That uncultured identified organisms span
3 a wide phylogenetic range, and their activities are
4 being investigated for MIC activities. In the
5 investigations of the corrosion test tanks, show that
6 organisms adapted to repository environments will
7 become established.

8 Okay. Next slide. So I would like to
9 move on then to electrochemical studies that we have
10 conducted to quantify the overall contribution of
11 microorganisms to corrosion, and then these types of
12 studies also offer an indication of the mechanism of
13 biogenic alterations to corrosion rates. Next slide.

14 So primarily for the studies thus far, we
15 have used a test cell that we have actually devised at
16 Livermore and this is composed of -- on the bottom of
17 this working coupon is the material that is being
18 tested, and it forms the base of the vessel.

19 And we either cook these with Yucca
20 Mountain microorganisms that we have isolated and
21 characterized, or we leave it sterile. So we
22 consistently try to run our experiments under both
23 sterile and non-sterile conditions to determine what
24 the biotic effects are. So you can subtract out all
25 the biotic effects.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE, N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 And the media that we have used in these
2 experiments again thus far is a fairly rich media and
3 sort of accelerated the whole process and produced
4 microbial growth.

5 And into this we have a platinum electrode
6 that is attached actually to potentiasac (phonetic),
7 and under an applied current, you can build up a
8 potential on this coupon and compare it to that of a
9 reference electrode, and it turns out that the
10 corrosion potential or the potential build-up is
11 directly correlated to corrosion rates.

12 So this is a means of actually measuring
13 corrosion rates in real time. Okay. The next slide.
14 So we incubate these for a period of -- in this case
15 up to about five minutes, and this is looking at -- and,
16 you know, I apologize, because when they reproduced
17 these overheads in black and white, I think you lost
18 like the green like the green and the red, and you
19 can't decipher.

20 But what this depicts is one of these
21 linear polarization studies with either carbon steel,
22 or Alloy-400, which is a copper nickel alloy. You can
23 see that under sterile conditions this is the Alloy-
24 400, a fairly corrosion resistant material.

25 Notice here that corrosion rates and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 microns per year are on a log scale, and so you have
2 very low corrosion rates under sterile conditions.
3 And yet when you add the bacteria, and that is the red
4 circles, and they appear, you can see that you have
5 increased corrosion rates on the order of 200-fold.

6 Similarly, with carbon steel, under
7 sterile controls, and that is the yellow squares, you
8 have a lower corrosion rate, albeit it's on the order
9 of one micron per year.

10 And it increases to about 8-fold, or I
11 think it is about 6-to-8-fold actually when you add
12 bacteria to the system. So in this way we are able to
13 actually establish what we call an MIC factor, or that
14 factor by which microorganisms increase the corrosion
15 rate of a given material.

16 And in this case, it increases the rates
17 of Alloy-400 almost to sterile, the level of the
18 sterile carbon steel. Next slide, please.

19 Okay. This is the same type of study, and
20 this time we are looking at probably most
21 interestingly Alloy-22 and stainless steel 304, as
22 well as I625, and what you see is the Alloy-22 under
23 sterile conditions, and non-sterile.

24 And you will notice here on the Y-access
25 that these corrosion rates are much lower than that of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

1 the Alloy-22, or I'm sorry, the Alloy-400 or carbon
2 steel. This being one of the reasons that we are
3 using Alloy 22, or not using it, but promoting it as
4 a possible candidate material for the corrosion
5 resistant barrier of the waste package.

6 And the bacteria, at least in this
7 experiment, don't appear to have that much of an
8 effect. I mean, they raise it by the order of two-
9 fold, and they have actually incorporated that MIC
10 factor into the current models, and the next slide --
11 oh, I'm sorry.

12 So at the termination of these
13 experiments, we did what was called an anodic
14 polarization test, and what this shows is three of
15 these materials, and again a sterile control, and
16 inoculated with Yucca Mountain bacteria.

17 And you can see that under a given
18 potential here that there is always a higher current
19 density with the Yucca Mountain bacteria, and this is
20 fairly consistent for altering materials.

21 This actually shows that the mechanism by
22 which these bacteria are causing these increased
23 corrosion rates is by accelerating the anodic reaction
24 or the dissolution of metal.

25 So we think that is how they are working,

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

1 and we are investigating that further. The next slide
2 is sort of a summation of the status. Again, for
3 example, the carbon steel, these are average corrosion
4 rates, and so what we have done is just under steady
5 state averaged all those points.

6 Again, a factor of about 6 or 7-fold under
7 sterile conditions, versus non-sterile, and then again
8 for Alloy-22, only by a two-fold difference.

9 Now, this may be somewhat of an under-estimate of
10 corrosion rates, because if you recall when I showed
11 you the set-up of this experiment, it is actually run
12 under batch conditions for about five months, and
13 although we have not measured the oxygen
14 concentrations, we think they are going anaerobic.
15 That would be fairly typical. They are not being
16 mixed or aerated.

17 And so we would expect that they would be
18 depressed or the overall corrosion rates. Now, the
19 actual MIC factor or ratio of sterile to non-sterile
20 may remain the same. But we are checking that out by
21 running these experiments under aerated conditions
22 presently. Okay. Next slide.

23 I don't want to make too much of this,
24 because this is a very preliminary result, but what we
25 did was to test at the termination when we tore down

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 some of these experiments what the solubility
2 concentration of alloy elements were in solution to
3 see if we could get any idea of how fast the metal was
4 going away, or which alloy elements might appear.

5 And what we saw in the case of Alloy-22
6 was that when it was sterile, we couldn't detect
7 either nickel or chrome in solutions, but when we
8 added the bacteria, we detected a noticeable amount of
9 chrome. This is in parts per million.

10 Now, this isn't to say that we are
11 actually getting selected dissolution of alloy
12 elements. It may be that everything does go away at
13 the same time, but that some of the alloy elements
14 reprecipitate.

15 So I don't want to make too much of this,
16 but what we are doing now is to -- that instead of
17 looking at what is left in the solution, we are
18 looking at what is left on the coupon, okay? And that
19 is a much better measure, using sputtering x-ray
20 photoelectron spectroscopy, we can actually
21 determine what the ratio of alloy elements is as we
22 sputter into the metal on a very high resolution.

23 So it is a much better measure of what is
24 going on with the mode of dissolution here. Okay.
25 Next slide.

1 So to summarize then these electrochemical
2 and dissolution studies, carbon steel shows an
3 increase in corrosion rates for the Yucca Mountain
4 bacteria and Monel shows even a greater MIC factor.

5 The Alloy 22 shows a lower increase in MIC
6 factor, only two-fold so far, and delineated MIC
7 factors require further investigations under more
8 representative, i.e., aerobic conditions.

9 And this is another aspect that I
10 neglected to mention, was that when you polarization
11 this, normally you use to measure a generalized rates
12 of corrosion, and MIC is usually characterized by what
13 is called a localized effect.

14 That is, it is more associated with
15 pitting and so forth. Now a better way to assess that
16 is using cyclic polarizations. So what we are doing
17 now, is that we have got some testing planned to
18 better estimate these localized corrosion effects.

19 Okay. To date, the anodic polarization
20 analyses demonstrate that microbes are causing an
21 increase in anodic activity; that is, metal
22 dissolution.

23 And that the MIC factors thus far
24 determined have been incorporated into a role model.
25 The next slide. Okay. Let me move on to our

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 accelerated materials testing program, and we are
2 actually doing three different types of testing for
3 this.

4 We have got a simulated saturated
5 repository environment that we call microcosm for
6 obvious reasons, although Milt may disagree, and then
7 we are doing peer culture studies and using organisms
8 with defined microbial activities.

9 And we are also doing some batch chemical
10 testing. So I will describe each one of these. Next
11 slide. These are simulated saturated repository
12 microcosms. They are fairly simple systems, but they
13 include what we expect would be all the elements of a
14 saturated repository.

15 So what we do is we feed the actual
16 microcosm environment with a formulation that is ten-
17 fold concentration of J13 ground water. We supplement
18 it with some glucose to accelerate the process, the
19 microbial growth, and we feed this at a very slow
20 rate, at about 2 mils an hour, into this vessel, which
21 contains aseptically collected and crushed rock.

22 And again we run these under both sterile
23 and non-sterile conditions. Again, sterile controls
24 are produced by eradiating the rock at 3 mega rads.
25 And into this we also put candidate material coupons

1 of waste package materials.

2 So that periodically we can withdraw the
3 coupons and look at the surfacial effects of the
4 bacterium. Next slide. This is just a picture of
5 what some of these microcosms setups look at. This is
6 the reservoirs, and these are being incubated at 30
7 degrees C.

8 We were running them presently at 30 and
9 at room temperature, and it goes through a pump into
10 the microcosms and out through a pump and into a waste
11 reservoir. Next slide.

12 And one of the things that we have been
13 able to do is that we when we withdraw coupons, we
14 look at them first just under fixed, and we fix them
15 with either glutaldehyde (phonetic) or we approximate
16 a critical point fixing.

17 But if corrosion products are evident, we
18 can image them using scanning electronscopy. And then
19 in this case it is carbon steel, and so the corrosion
20 products build up rather quickly and these are just
21 different mil basis that we have been able to identify
22 through facial chemical effects. Next slide.

23 An in fact this is just looking at the
24 SEM, and we can identify the morphology of these
25 corrosion products, and we are using the EDS, and we

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 can identify their elemental makeup, and we have been
2 able to do x-ray refraction and actually identify the
3 mineral phases.

4 So we can match these up, and pretty much
5 not only identify the mineral phases, but what likely
6 they originate from. For example, the silica in this
7 case comes from the rock that we have incorporated
8 into the system. Next slide.

9 Now, despite the fact that these systems
10 are being fed continuously, and you are continuously
11 getting a dilution of whatever chemical effects are
12 occurring in that microcosm.

13 And you are also washing out any of the
14 chemical alterations. We have been able to detect
15 and I don't want to make too much of this either,
16 because you are looking at parts per billion here, but
17 this molybdenum in the efflux, that is, in the angelus
18 phase of a microcosm containing Alloy 22,
19 and under non-sterile conditions at 30 degrees.

20 And we really are not seeing the same
21 thing with the sterile controls or the new metal
22 controls, or even the non-sterile at room temperature.
23 But again we are investigating this further. Next
24 slide.

25 Okay. When we withdraw these coupons, as

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 I said, first we fix them and image them, and then we
2 clean them. And we use high resolution imaging
3 techniques and in this case atomic force microscopy,
4 to look at the surface and to see if we can discern
5 any differences due to the presence of bacteria in the
6 rock.

7 And here you see that this is what we
8 start off with. The surface was sanded to 600 grid
9 initially, and so it is fairly rough, and that is what
10 these striations are. Again, I want to emphasize that
11 you are looking at a very small piece of property
12 here. This is a hundred-square microns, okay?

13 And the Z-axis is 3 or 3-1/2 microns,
14 okay? So it is a very high resolution. The sterile
15 controls for microcosms containing just the sterilized
16 rock, you see a kind of flattening of the striations.

17 And in the non-sterile coupons, these are
18 all incubated for a year, and the non-sterile coupon,
19 you can see that there appears to be a kind of
20 redistribution of the roughness, and it may be
21 something like nano to micropitting. The problem here
22 I think with this analysis is you are starting with a
23 rough surface, and you are ending with a rough
24 surface.

25 So it is pretty darn difficult to get your

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealgross.com

1 arms around quantitatively around what is happening.
2 So what we are doing now to remedy that situation is
3 to incubate mirror finish coupons. So that means that
4 we start with a much flatter surface, and if we see it,
5 erupting, we can at least quantify it.

6 Next slide. Okay. This is looking at a
7 non-sterile coupon of Alloy-22 going through two years
8 in a non-sterile microcosm, and 1 year or 1-1/2 years,
9 2 years. So again there does seem to be some effect,
10 but they are small.

11 Again, the Z-axis is 3 microns, but they
12 are clearly not rare events. I mean, we can zero in
13 on these regions without too much difficulty. But we
14 need to get a better handle on the distribution of
15 these events as well. Next slide.

16 So to summarize the microcosm experiments
17 then, we have got a system that allows analysis of
18 material effects in an environment that includes
19 essential elements of a repository. That the effects
20 of the microorganisms can be discerned by comparison
21 with a biotic controls. And we also have no metal
22 controls, and so we can look at the effects of the
23 rock top.

24 We have combined chemical, analytical, and
25 imaging techniques to quantify specie and corrosion

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 products. We also do gravimetric analysis of these
2 materials, which permits the estimation of corrosion
3 rates and effects.

4 And there appears to be some nano effects
5 of microbial activity on Alloy 22, but quantification
6 and distribution of corrosion needs to be analyzed
7 with mirror finish coupons, and then the results can
8 be incorporated into the corrosion models.

9 Next slide. So we are also doing some
10 pure culture work, and what I did was to go through a
11 kind of systematic analysis of Alloy-22 and titanium
12 primarily may most likely be susceptible to microbial
13 corrosion.

14 And what I came up with is -- and then
15 what we did was to pick organisms that have these
16 specific activities, and grow them in peer culture.
17 So this is what we call a microbiology continuous
18 culture.

19 So you are constantly feeding the
20 bacteria, and grow them under optimal growth
21 conditions, okay? So what we are doing is producing
22 this very vigorous high-density culture, and then we
23 picked these specific bacterium. Clostridium produces
24 hydrogen at point high rates.

25 And in order to see if they generate

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 hydrogen embrittlement, and we are also testing a
2 sulfate reducing bacteria that produces sulfide, and
3 it also happens to grow in high salt environment.

4 We are looking at a thiobacillus organism
5 that generates sulfuric acid when grown in reduced
6 sulfur medium, and we also are taking a mixture of
7 Yucca Mountain fungi that we isolated, and we are
8 growing that in some rich broth to see if the
9 generation of organic acids is going to affect
10 corrosion of these materials. The next slide.

11 So this is the microcosms, except that now
12 we have just -- we don't have any rock in these
13 studies, but rather we have these defined organisms in
14 separate experiments, and they are being fed with
15 media that is conducive to generating these possibly
16 deleterious end products, and in the reactors we have
17 got trays, Teflon trays containing both titanium Grade
18 7 and Alloy 22.

19 And of course they are being drained at
20 the same rate that they are being fed at. The next
21 slide.

22 This is just a picture of a c.
23 acetobutylicum bioreactor. It is about a one liter
24 vessel, and this is actually contained in the
25 anaerobic glove box, because these are anaerobic

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 organisms that are grown in an nitrogen atmosphere.
2 Next slide.

3 Okay. This is a picture or an SEM image
4 I should say of the biofilm formation on a titanium
5 coupon in a sulfate reducing bioreactor. And you can
6 see that on the little rods here that they are
7 microorganisms. They are colonizing the surface, and
8 on the right this is actually a picture of or an image
9 of that polysaccharide matrix that I mentioned
10 earlier.

11 And you have to of course dry the samples,
12 fix and dry them in order to see them in the SEM, and
13 so when you dry them, the film tends to crack them,
14 and that is what you are seeing there. But it is
15 definitely evident and present. And the next slide.

16 So this is the sulfuric acid producing
17 culture, and after seven months we withdrew some of
18 the coupons, and surprisingly we actually found some
19 dissolution of titanium from the surface.

20 This is again what we started with, AFM
21 images again. This is in a sterile control and that
22 is just incubated in a bisulfate medium. And it looks
23 fairly degraded when we looked at the same, or the one
24 that was exposed to culture.

25 And we actually found that we precipitated

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 the titanium in the reactor, and the increasing
2 roughing was also confirmed by doing what is called a
3 root mean square analysis. Root mean squares are an
4 index of surface roughness, and you can see here with
5 the titanium that you actually increase the surface
6 roughness.

7 But fortunately with the Alloy-22 that it
8 didn't seem to have any effect. So that was a good
9 thing. But this isn't actually the first report of
10 MIC of titanium. People have looked for it for a long
11 time, but they never used quite these conditions. The
12 next slide.

13 So the summary of our pure culture studies
14 so far is that we can analyze the effects of specific
15 deleterious metabolic products on material
16 performance, and it permits the determination of the
17 upper limits of generation of these end products.

18 We are actually establishing that now, and
19 we are doing things like measuring the organic acid
20 concentrations of several organic acids, including
21 those that have been recently found by the USGS in
22 pour water form the site.

23 And it establishes some kind of upper
24 bound so that we can incorporate those into models for
25 the production of these end-products. And despite the

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 fact that there is a continual input and output into
2 the system, a steady state is gained, and I didn't
3 really show this slide, but we have been able to see,
4 for example, titanium dissolution again in our
5 clostridium CW2 reactor.

6 So we can actually see a surfacial
7 analysis of the material coupons is now ongoing. Okay.
8 The next slide. I just lastly wanted to mention a set
9 of experiments that we have just recently initiated,
10 and I wanted to get past this dissolution and washing
11 sort of issue that is connected with continual flow
12 systems.

13 What we have done is to start some
14 experiments under batch conditions so that we can look
15 at the build up or accumulation of either alloy
16 elements if they are being solubilized or of the
17 metabolic or alterations to ground water that the
18 microorganisms are generating.

19 And so in these experiments, we are using
20 crushed tuff and our simulated J-13 ground water, and
21 we can use either anaerobic or aerobic atmospheres.

22 And we think that we are actually using
23 Alloy-22 foil and the reason that we are doing that is
24 to sort of increase the surface area and the mass
25 ratio. So that if these materials are actually being

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealgross.com

1 corroded, we can detect them more readily by just
2 having more surface area being exposed in the
3 experiment.

4 And we can -- and, of course, we always
5 run our sterile controls with or without organisms.
6 We are also running with them without a carbon source.
7 And we are analyzing periodically the generation of
8 sulfide acids with a waste package alloy elements.

9 So it is sort of looking at all these
10 different alloytes so that we can get a better picture
11 of what the change in chemistry is both for the alloy
12 that we are testing, as well as the ground water. The
13 next slide.

14 So just to summarize overall then of our
15 MIC studies to date, we are looking at the potential
16 for MIC to occur, and that has been affirmatively
17 determined.

18 We are looking at the conditions for
19 microbial growth, which have been established, and
20 then coupled with thermo hydrological modeling, and
21 this establishes when MIC may become a factor for
22 microbial effects.

23 We have generated a roster of organisms
24 extant at the Yucca Mountain site and also organisms
25 that may colonize the repository. And then if we --

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 and answering that why question, coupled with their
2 associated metabolic activities, this information will
3 allow what MIC activities may be relevant to waste
4 package corrosion.

5 And initial MIC factors have been
6 determined, and establishing the overall contribution
7 of microorganisms to waste package corrosion, and we
8 are doing further testing on that, and under other
9 conditions.

10 Our dissolution rates and corrosion modes
11 of engineered barrier materials are being determined,
12 and the upper limits of deleterious bacterial end
13 products and their effects on these materials are
14 being established.

15 And lastly the effects of the Yucca
16 Mountain groundwater are currently under
17 investigation. So with that, I will conclude my
18 presentation and invite any questions from the panel.

19 CHAIRMAN HORNBERGER: Thank you, Joanne.
20 Milt, as our MIC expert, would you like to go first?
21 Well, Ray, do you have any questions?

22 VICE CHAIRMAN WYMER: First, let me say
23 that it looks like a very nice work, and it is a lot
24 more than I have seen up to this time, and you are to
25 be congratulated on the scope of your studies, because

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealgross.com

1 they are very broad in trying to cover all the
2 parameters of interest.

3 DR. HORN: Thank you.

4 VICE CHAIRMAN WYMER: I do have some
5 questions that you probably have not had enough time
6 to do research on to answer yet, but let me go ahead
7 and fire away.

8 First, I wondered about the potential rate
9 of bacteria entering the repository by whatever route
10 that they enter over a long period of time, and
11 whether there is enough there that it makes any
12 difference.

13 DR. HORN: Well, you know, it doesn't take
14 very much to start with to generate a lot, because
15 they divide by binary fusion. So they grow at an
16 incredibly high rate if the conditions are right.

17 VICE CHAIRMAN WYNER: If the nutrients are
18 there?

19 DR. HORN: Yes, and I think -- well,
20 pretty much the assumption is at this point in the
21 field is that organisms in the deep subsurface
22 primarily are -- and they either originate when the
23 rock was laid down, or they infiltrate with incoming
24 ground water.

25 So in this case, we would be looking at

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 infiltrations. So I think that the number of
2 microorganisms that come in absent ventilation, but
3 that is another issue, will be primarily dependent
4 upon infiltration items.

5 VICE CHAIRMAN WYMER: And I suppose the
6 nutrients have to come in with them?

7 DR. HORN: Yes, except that so far we have
8 found that they don't need very much to grow. If we
9 give them ground water, even unamated within a carbon
10 source, that they appear to be able to pick up and
11 grow fairly readily.

12 VICE CHAIRMAN WYMER: Of course, they all
13 need a phosphate backbone, and so --

14 DR. HORN: That's true, that is an
15 essential element. Now, there is a about 200 ppm
16 phosphate in the rock, which I am sure that many of
17 you are aware of. And when we don't put -- and I
18 didn't show these experiments, but when you don't add
19 phosphate to rock, we are presuming that the phosphate
20 that they are growing on, they are dissolving from
21 rock. And there is actually a good deal of evidence
22 in the literature to suggest that bacteria can readily
23 dissolve phosphate from the rock.

24 VICE CHAIRMAN WYMER: Okay. There is a
25 question of the mixtures of the bacteria comes up, and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealgross.com

1 you did studies with typical Yucca Mountain mixtures
2 of bacteria.

3 DR. HORN: Right.

4 VICE CHAIRMAN WYMER: But then you are
5 doing the peer culture studies, too.

6 DR. HORN: Right.

7 VICE CHAIRMAN WYMER: It looks to me like
8 some of these bacteria would be fighting each other,
9 and they are reducing bacteria, and they are oxidizing
10 bacteria.

11 DR. HORN: Yes. Yes. And that occurs in
12 subsurface environments. As an example, there are
13 methane producing bacteria that attack CO2 and reduce
14 it to methane, and then there are methane oxidizing
15 bacteria that use the methane as a carbon source and
16 generate CO2. So, analogously, you know, manganese
17 oxidizers.

18 VICE CHAIRMAN WYMER: And in the
19 repository the question is who wins?

20 DR. HORN: Well, actually, in this case I
21 don't really think that they are fighting each other,
22 because in a way they are really facilitating each
23 other's physiology. In other words, if you are a
24 manganese oxidizer, you need reduced manganese, and so
25 if you have a manganese reducer that is producing that

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 as an energy source for the manganese oxidizer, that
2 guy kind of has it made.

3 So I think in some sense that if you look
4 at the overall storic-metrics, as a chemist, I can
5 understand how you think. But from a microorganisms
6 point of view, this is a good thing, because you have
7 got available sub-stain.

8 VICE CHAIRMAN WYMER: And you have, for
9 example, that you are either making sulfite, or you
10 are making sulfate?

11 DR. HORN: Right.

12 VICE CHAIRMAN WYMER: You are not making
13 both of them.

14 DR. HORN: Yes, the sulfite oxidizing
15 bacteria are actually anaerobic. And ultimately these
16 things are striated according to their environmental
17 micro-niche.

18 So, for example, the sulfite generating
19 bacteria are anaerobic. And then you see this, for
20 example, in sediments in marine sediments, where you
21 have a lot of sulfate and sea water, and you have got
22 a lot of sulfate generating bacteria in sea water.
23 But you get right into the sediment and then you get
24 very anaerobic. You only have to get down a couple of
25 millimeters and then you get sulfite generation.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE, N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 VICE CHAIRMAN WYMER: In a waste package,
2 you are probably going to have one or the other.

3 DR. HORN: Well, in even that, in these
4 binner films, you have very diverse microenvironments.
5 So, for example, at the top, you can have an oxidizing
6 environment, and then the oxygen concentration pops
7 precipitously as you go towards a metal surface.

8 And so you can have these sort of micro-
9 niches, where things that have very diverse
10 physiologies can actually exist side by side. So I
11 know that it is sort of counter-intuitive, but
12 apparently that has been shown.

13 VICE CHAIRMAN WYMER: Actually, I have
14 argued in the past for reducing environment, and what
15 is the repository in localized areas which supports
16 the oxidation.

17 DR. HORN: Yes, and from a micro logical
18 point of view, everything runs slower under anaerobic
19 conditions. You just don't get as much energy out of
20 the anaerobic metabolism. And so from that point of
21 view, I think an anaerobic reducing environment is
22 sort of better.

23 VICE CHAIRMAN WYMER: Now, what about
24 temperature effects? How do these --

25 DR. HORN: Sure, superimpose them.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 VICE CHAIRMAN WYNER: Are you planning
2 experiments at several temperatures?

3 DR. HORN: Yes, we found some sort of
4 crude kind of -- well, just kind of under anaerobic
5 conditions moving the temperature up. We have not
6 found much growth after about 60 degrees, but just the
7 organisms that are extant in the rock.

8 Of course, we know that there are
9 organisms --you know, those that grow in hot springs
10 and down in the smoken vents in the deep sea that can
11 exist up to temperatures -- I think about the upper
12 limit for life is about 120 degrees C.

13 We are not sure whether we are seeing any
14 of those organisms. So far we haven't found any. We
15 are still at the beginning of testing the tanks, and
16 that is one of the reasons that I think those test
17 environments are going to be really interesting to
18 see, and if there are any floating around, are they
19 going to become established there.

20 Because the canonical thought in
21 environmental biology is that things will grow and
22 become established if they are adaptive to a
23 particular environment.

24 So it is not totally beyond the realm of
25 possibility that we will see these things growing and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 --

2 VICE CHAIRMAN WYMER: And it could be
3 quite a while before the surface of the waste package
4 will get down to 60 degrees or 70 degrees.

5 DR. HORN: And even more than temperature,
6 I think it is going to be water availability, because
7 we know that there are things that can grow at high
8 temperature. But water availabilities -- I mean, life
9 needs water, and that is the bottom line.

10 And so we really are not expecting
11 microbial growth until water reenters the repository,
12 but the water availability is tied directly to the
13 temperature of radiation. So as the temperature
14 drops, water increases, and radiation drops.

15 So those three factors are really tied
16 together, but since water seems to be the primary
17 riveting factor, we have kind of picked on that as the
18 kind of switch.

19 VICE CHAIRMAN WYNER: And on the waste
20 package, you do have both temperature and radiation
21 fighting you pretty good?

22 DR. HORN: Right. Absolutely, and those
23 things will prevent the growth directly on the waste
24 package for thank god a good long length of time.

25 VICE CHAIRMAN WYMER: John Garrick has

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 given me permission to ask his so what question.

2 DR. HORN: Yes, so what, and I was
3 expecting that.

4 VICE CHAIRMAN WYNER: Just take your
5 general corrosion rates from one of your viewgraphs,
6 and you come up with maybe for the Alloy-22 a couple
7 of millimeters in 10,000 years, and for stainless
8 steel, 3 or 4, or maybe twice that.

9 DR. HORN: Right.

10 VICE CHAIRMAN WYMER: Maybe for 3 or 4
11 millimeters, maybe 10,000 years.

12 DR. HORN: Right.

13 VICE CHAIRMAN WYMER: That doesn't get
14 through the waste package. So let me ask you what is
15 your opinion about the significance of the microbial
16 on the waste package?

17 DR. HORN: Well, you know, I mean, we
18 didn't design these experiments to prove that bacteria
19 were going to be a problem. We designed them to
20 answer that question will they be a problem.

21 So I think under the conditions of this
22 particular experiment, we have shown that it won't be
23 a problem, which is a good thing. Now, like I said,
24 these may be depressed somewhat because of the
25 conditions under which we ran these experiments, and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 that's why we are repeating them.

2 And we are also doing some alternative
3 types of testing that are better at looking at sort of
4 localized pitting, which is what bacteria are really
5 known to do.

6 VICE CHAIRMAN WYMER: Well, thank you very
7 much. That is really nice work.

8 DR. HORN: Thank you.

9 DR. GARRICK: Just continuing with that a
10 little bit. I am curious about how much microbial
11 corrosion you would have to have in order for that as
12 a waste package integrity threatening mechanism to be
13 competitive with, for example, the current corrosion
14 model, which is a diffusive transport model that
15 eventually leads to intergranular corrosion cracks in
16 the absence of water, and only in the presence of an
17 assumption about a film.

18 So there is no water until the drip shield
19 begins to fail, which according to the current model
20 doesn't occur for several tens of thousands of years.

21 So what is the relevance of all of that?
22 If you have already got a failed waste package in the
23 absence of water, how can we become concerned about a
24 contribution that comes from a phenomena that has to
25 be in the presence of water?

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 DR. HORN: So you mean that you can't kill
2 it twice?

3 DR. GARRICK: Yes.

4 DR. HORN: You know, I might just defer to
5 one of my colleagues who has more familiarity with
6 some of the other modes of corrosion. Dan McCrite has
7 been in the program for a long time, and Dan, do you
8 want to give that one a crack?

9 MR. MCCRITE: Well, one of our major
10 concerns with the MIC factor is what it would do to
11 localized corrosion, and possibly stress-corrosion
12 cracking, again in an anaerobic setting, because in
13 those cases the MIC factor would be a lot more than
14 just two. It would be in the thousands.

15 And that is analogous to some of the
16 industrial or field studies that components have
17 failed by MIC components, particularly the stainless
18 types of materials, like stainless steel and so forth.

19 But when MIC is a significant factor in
20 your corrosion, it is usually in a crevice or around
21 the weld. And today we have not studied all those
22 things with MIC as also a component. We have done a
23 lot of testing in just purely a biotic condition, but
24 we plan to also do those same kinds of studies with
25 MIC components.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 It is a little harder test to do because
2 obviously we have to keep the microbes alive during
3 the duration of the experiment. So also have had some
4 problems in getting suitable samples, especially
5 welding samples, where we will carry those experiments
6 out.

7 So the data has been essentially the
8 effect of MIC on general corrosion, which really isn't
9 much of a major problem with Alloy C-22, whether it is
10 biotic or a biotic. But we think that if there is an
11 effect that that it is going to be in localized
12 corrosion and stress corrosion cracking, and those
13 experiments remain to be done, particularly with MIC
14 as a component.

15 DR. HORN: And just to add a little bit to
16 that, is that it has been established that
17 microorganisms really like weldments, and so we are
18 pretty anxious do these same experiments and look at
19 the differential effects on weldments.

20 DR. GARRICK: Many years ago, when the
21 WHIP project was going through a stage similar to what
22 the Yucca Mount Project is going through now, one of
23 the big worries was gas generation.

24 And one of the big anxieties about gas
25 generation, at least in the early days, was microbial

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 induced corrosion on the drugs, et cetera, et cetera.

2

3 Eventually that issue seemed to go away,
4 and the experts on microbial corrosion came forward
5 and essentially indicated that this was not a real
6 issue.

7 Is the information that led to that
8 conclusion or the technology that was associated with
9 that effort -- and I realize that geology is very
10 different, and the materials are very different,
11 except for iron. But has that information been a part
12 of your --

13 DR. HORN: You know, we have not worried
14 about it too much, because we really have an open
15 system here. I mean, are you talking about within
16 waste packages?

17 DR. GARRICK: Yes.

18 DR. HORN: Well, I am not too worried
19 about within waste packages, because I think
20 everything is just going to be killed there, and the
21 wooden facility, since it is a low level radiation
22 environment, they were much more susceptible I think.

23

24 So once bacteria can recolonize the inside
25 of a waste package, it has already been breached, and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 so already you have defined an open system. And we
2 know that it is not like in the Canadian version or
3 their design.

4 It is a very tightly packed system. I
5 know that they are also worried about gas generation
6 and pressure buildup, but I think the inside of the
7 packages are going to be sterile. If anything ever
8 gets in there to recolonize, by definition it has to
9 be breached.

10 So you don't have to worry about pressure
11 build up on the inside of the cans. And then on the
12 exterior of the packages, I don't think we have to
13 worry about pressure buildup, because we essentially
14 have a breathing open system.

15 DR. GARRICK: I wasn't thinking of it so
16 much as having to worry about pressure buildup. I was
17 more thinking about it at the mechanistic level, and
18 the mechanisms.

19 DR. HORN: Well, we have this one
20 experiment going right now, and I guess hydrogen
21 embrittlement is more of a concern for titanium, and
22 so we have got this hydrogen producing culture that
23 generates hydrogen like nobody's business.

24 And so we are actually testing whether we
25 can induce hydrogen embrittlement by these organisms.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 It is kind of a worse-case scenario, and then looking
2 at the mechanical effects, and we will be doing the
3 same on the surface to see if there is actual hydrogen
4 invasion as a result of microbial generation of
5 hydrogen.

6 So from the literature is real ambiguous
7 on this topic. Nobody has ever definitely seen MIC
8 induced hydrogen embrittlement.

9 DR. GARRICK: And just a final comment.
10 While you are doing these experiments are you also
11 thinking in terms of possible methods of mitigating
12 microbial corrosion?

13 DR. HORN: You know, I think that was sort
14 of -- you know, because anything would have to be a
15 kind of engineered approach, and I think everybody is
16 very hesitant to -- you know, for example, I think
17 somebody really early on suggested, well, why don't
18 you add a micro side, and I think over a 10,000 year
19 period that everybody is fairly convinced that just is
20 not a practical approach.

21 So what we are doing is trying to rely on
22 the materials to resist corrosion, rather than trying
23 to get rid of the bacteria.

24 DR. GARRICK: Okay. Thank you.

25 CHAIRMAN HORNBERGER: Joanna, I am still -

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE, N.W.
WASHINGTON, D.C. 20005-3701

1 - I am interested in how the results actually get
2 scaled to the repository, and again in this sense, I
3 asked you the question about the source of energy to
4 run this system.

5 And you replied, well, it could be on a
6 chemoanotropic base.

7 DR. HORN: Right.

8 CHAIRMAN HORNBERGER: Or it had to come in
9 with the water. In either case it strikes me that the
10 10 to the 4th and 10 to the 5th bacteria per gram of
11 rock is not a big thick biofilm.

12 DR. HORN: Right.

13 CHAIRMAN HORNBERGER: And I can't see that
14 you are going to bring an energy source in with the
15 waste package.

16 DR. HORN: I guess the thing that concerns
17 me is that when you do add that ground water, even
18 without a carbon source, you see up to 10 to the 8th
19 bacteria, and that is actually per ml.

20 That is actually the platonic bacteria
21 that are floating around in the aqueous phase, and
22 bacteria like to stick to things. So it is at least
23 that many, and there is probably more stuck to the
24 rock.

25 DR. HORNBERGER: Then why do you only

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 measure 10 to the 4th and 10 to the 5th in the rock?

2 DR. HORN: Because you don't have water
3 there now, okay? So right now there is 10 to the 4th
4 to 10 to the 5th, but they are looking at perturbing
5 the system and we are going to drive the water away
6 presumably and then it is going to come back.

7 And I think the infiltration rates are
8 going to be what determines the microbial growth.

9 CHAIRMAN HORNBERGER: So basically you are
10 looking at this as a potential problem in the
11 superfluvial, where the infiltration rates are higher?

12 DR. HORN: Precisely.

13 MR. LEVENSON: One of the things that I
14 have been asking about I can't seem to get an answer,
15 as to why with the present design the inner-container
16 is stainless steel instead of just iron or carbon
17 steel, from just the standpoint of microbial
18 corrosion, or microbial enhanced corrosion.

19 Is there any advantage to stainless steel,
20 as opposed to ordinary steel?

21 DR. HORN: Well, right now we are really
22 not taking any credit for the inner-package. It is
23 just as a structural support for the outer package.

24 MR. LEVENSON: I know that they are not
25 taking any credit, but as a taxpayer, I am paying for

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 it.

2 DR. HORN: Yes. Well, I think I am going
3 to call on Dan for this because he has been around the
4 carbon steel days, and has more of a justification for
5 the switch.

6 MR. MCCRITE: Just arguing from general
7 corrosion to stainless steel, the general corrosion
8 rate will be under almost any circumstance will be
9 less than carbon steel.

10 So one of the reasons for picking
11 stainless steel for the inner-barrier than carbon
12 steel was that if and when the outer barrier is
13 breached, if it were stainless steel, it would corrode
14 still much the same way as the Alloy-22 did by some
15 localized mechanism.

16 If it is carbon steel, it will corrode
17 much more vigorously, and probably with some
18 volumetric change, and so in which case the whole
19 package would stand to rupture open, and more so if it
20 were a more corrosion resistant material inside.

21 So again our concept of the corroded waste
22 package is that we would never have lots and lots of
23 area exposed, and that it would be just crack by crack
24 and tit for tit. It would be a very small, small
25 amount of actual area that was corroded through and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 where the water could penetrate through, rather than
2 a very large area.

3 So we thought that the stainless steel
4 inside would help in that argument.

5 MR. LEVENSON: But the argument that you
6 are not making, since you are taking zero credit for
7 it.

8 MR. MCCRITE: That's right from the
9 containment point of view, but thinking that other
10 people in their analyses may want to consider the
11 pathways of water in and the pathways of radio
12 nuclides out.

13 And that this is not our argument in the
14 containment group, but as to others as being a total
15 barrier system.

16 CHAIRMAN HORNBERGER: Questions from the
17 staff? Mike.

18 MR. LEE: Mike Lee, ACNW staff. The Yucca
19 Mountain rock, is that just the Calico Hills crushed
20 tuff?

21 DR. HORN: Actually, I think it is Propone
22 Springs tuff. Actually, we have isolated it from
23 where we excavated it from Alco-5, which is in the
24 same horizon as the repository.

25 NR. LEE: Okay. So it is a pretty fresh

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 sample then?

2 DR. HORN: Yes, and I just want to mention
3 that in these studies we really have not made a
4 distinction between organisms that are introduced as
5 a result of construction activities, and those that
6 are extant. So we really have not separated those
7 out, because I don't really think it makes any
8 difference to the project in the end.

9 I mean, they are going to have to deal
10 with the whole thing. So we have tried to get it, and
11 we have done both getting it off the surface of the
12 walls, and inside as well.

13 MR. LEE: And my other question is that
14 there is going to be a lot carbon steel possibly in
15 the repository as a result of roof enforcement and
16 things like that, and rock holes, and stuff.

17 Is there any plan on looking at the
18 effects of microbial induced corrosion there?

19 DR. HORN: Well, we have done some of
20 those studies and we did some lineal polarization and
21 this was primarily at the time when carbon steel was
22 the outer layer of the corrosion at the waste package.

23 But knowing that, there are other elements
24 of the engineer barrier system that are close to steel
25 and that's why we characterized the corrosion products

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 and looked at the overall rates of corrosion.

2 But more recently we have frankly been
3 focusing in more on the Alloy 22 and titanium, because
4 it is just more of a priority.

5 CHAIRMAN HORNBERGER: Andy.

6 DR. CAMPBELL: Getting to the water issue,
7 how much water do you need? We took a tour of Yucca
8 Mountain yesterday and went into the cross-drift, and
9 saw and heard discussion about mold spores. In fact,
10 we all had to sign our life away saying that we would
11 not hold DOE responsible.

12 Mold grew rapidly in that environment once
13 it was closed up. Now, there is no liquid water there
14 that is dripping as far as you guys and as far as DOE
15 knows. But there is a heck of a lot of moisture there
16 in terms of humidity and condensation.

17 And even without a punctured drip shield,
18 as the waste packages cool, do you believe that there
19 would be sufficient moisture on the surface of the
20 waste package that these organisms could grow?

21 DR. HORN: Yes, I am well aware of the
22 cross-drift issue, because when it first came up it
23 was primarily the S&H issue, and they brought us in to
24 do this survey of fungi. They were growing on just
25 about everything organic down there.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE, N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealgross.com

1 And so if you look at the literature,
2 fungi are a little more justification resistant than
3 bacteria, but it is on the order of 95 percent Rh.
4 Now, that doesn't include -- you know, there is some
5 discussion that as salt brines actually build up on
6 the package, or for that matter on the drip shield,
7 that the deliquescence point or that point of relative
8 humidity, where the salt actually absorb water, and
9 produce a water film, can actually be at a lower
10 relative humidity than that turnaround point for
11 general microbial buildup.

12 So I think there are those two issues.
13 Yes, we are saying 90 or 95 percent Rh, but that
14 doesn't include the deliquescence point of the salt.
15 Now, I just want to point out that if they grow in
16 these mines, they have got to be very salt resistant
17 organisms.

18 And those do exist, and I live in San
19 Francisco, in the Bay Area, and if you have ever flown
20 into South Bay, you will see these big salt ponds that
21 are all red, and the reason that they are red is that
22 there are organisms called halo bacteria that are very
23 salt resistant, and that have these red pigments that
24 grow in there.

25 So, so far we have not seen it in halo

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 files, or what we call halophytic or salt loving
2 bacteria in the repository, or we have not seen them
3 in the test kits either. So that is good news.

4 So how much water? Well, if it is free of
5 relative humidity, then probably we are talking 90 to
6 95 percent, and all you need is a film. You don't
7 need it to be dripping.

8 But then you might start at relative
9 humidities if you have halo tolerant bacteria and you
10 get this deliquescence on the packages or other
11 surfaces.

12 MR. LEE: One other comment. In another
13 life I actually worked on hydrothermal vent systems,
14 and marine sediments, and in answer to Ray's question,
15 you generally see some sort of divergence of the
16 methane producers, versus the sulfide producers,
17 versus the sulfate producers, and sulfide oxidizers,
18 excuse me.

19 And you see a stratification in sediments,
20 but frankly you see a lot of cross-over and you see
21 mixtures of bacteria that in theory should not be
22 growing together and they are, and the usual
23 explanation was that you have micro-environments that
24 favor either more reducing or a more oxidating
25 environment.

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

(202) 234-4433

www.nealrgross.com

1 And the other thing is that hydrothermal
2 vent systems have these wonderful communities of life
3 moving around and they are all living on essentially
4 the bugs that oxidize sulfite, as a completely
5 chemorodictrophic system.

6 And so once you get one growing, pretty
7 soon you colonize it with all kinds of other things,
8 and the last thing is to remember that the reason we
9 have oxygen in the atmosphere is because of bugs. So
10 no matter where they are, in the earth, or even deep
11 into the earth, one finds bacteria, and they are
12 living off of some sort of energy source.

13 CHAIRMAN HORNBERGER: Don't forget there
14 has to be an energy source, and there is a pretty darn
15 good energy source at those vents. Any other
16 questions nor comments from anyone?

17 MR. SHETTEL: Don Shettel for the State of
18 Nevada. Are you planning to look at any other water
19 compositions besides J-13?

20 DR. HORN: Well, the problem is that you
21 look at more materials and more water -- well, we are
22 looking at high reactions and other pHs in the context
23 of what we saw in corrosion tanks.

24 MR. SHETTEL: Well, does that mean like 10
25 times --

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 DR. HORN: Actually, the more
2 concentrated, it is a thousand times. We are
3 attempting to expand the matrix somewhat, but it is
4 just difficult because a lot of these are long term
5 tests, and they take a lot of maintenance, and how to
6 gauge that is difficult to accomplish.

7 MR. SHETTEL: Yes, but port water has
8 higher sulfate and nitrate, which might be important.

9 DR. HORN: Well, already we know that the
10 ground water has enough sulfate and nitrate. You
11 almost can't have too much sulfate and nitrate for
12 bacteria, because that is what we call macronutrient.

13 I mean, it is in all your proteins, and
14 your DNA and all the membrane proteins. So you need
15 a lot of phosphate and sulfate, nitrate, or nitrogen,
16 and sulfur, as well as a carbon source. And those are
17 the four things that you need a lot of.

18 So to increase it 10-fold wouldn't be a
19 bad thing. It wouldn't prevent microbial growth. We
20 are more concerned with nitrate concentrations being
21 depleted by bacterial growth because it turns out that
22 nitrate kind of combats chloride. Chloride generates
23 corrosion, and nitrate sort of emolliates that effect.
24 So the nitrate and chloride concentrations are
25 important, and those ratios are important and is

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 something that we are interested in looking at.

2 MR. SHETTEL: And my next question is that
3 I know that you are going to try different
4 temperatures, which is good, but when the coupons are
5 submerged below the solution though, that is okay for
6 anaerobic bacteria, but with the aerobic ones, you
7 should be trying perhaps to drip the water on the
8 coupon.

9 DR. HORN: We have thought about doing
10 that. Actually, in the tanks, they are very
11 vigorously mixed and so it is an area of environment,
12 and it is not a closed system. It is generally
13 closed, but it's not like it is sealed. And then
14 these things are being continuously mixed.

15 MR. SHETTEL: And that would mimic a thin
16 film, and you might find on the canister?

17 DR. HORN: Right. And when we sample the
18 tanks, we actually swipe the surfaces, too, to see if
19 we can expect more to be attached to surfaces.

20 CHAIRMAN HORNBERGER: I don't want to
21 interrupt, but I don't want to carry on too much into
22 deeply exactly what is measured, and what the plans
23 are, because a lot of this can be done off the record.
24 Is there another question?

25 MR. TYNAN: Mark Tynan, from DOE. I was

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 going to try to lead you to the final question. If
2 you look at the species that you have identified from
3 the rocks at Yucca Mountain, how do they differ from
4 the ones that I find in my aquarium at home?

5 DR. HORN: Well, your aquarium is a little
6 bit different environment. But in your garden, I
7 would say they are a lot closer, although generally
8 there is a lot more organic material in your garden.

9
10 MR. TYNAN: How about on the surface area
11 at Yucca Mountain?

12 DR. HORN: You know, we haven't actually
13 looked at that, and that is one of the things that I
14 have been wanting to look at, particularly in like the
15 playus (phonetic), these dried up salty lakes and so
16 forth in that area, because that may be a good
17 mimicking environment for these surface grinds that
18 they are expecting may develop on the surface of the
19 packages. But great question. I would love to do the
20 experiment.

21 MR. TYNAN: From what you have looked at,
22 your factor of two on C22, is that incorporated in the
23 TSPA SR?

24 DR. HORN: Yes, it is.

25 MR. TYNAN: And is it included in SSPA and

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 the FEIS calculations?

2 DR. HORN: Yes.

3 MR. TYNAN: And so you are adding some new
4 things in the future that will be available throughout
5 that will be available for LA that you indicated --

6 DR. HORN: Absolutely. And I know that a
7 lot of this data is in the data bank, and we very
8 shortly are going to be putting a lot into it.

9 MR. TYNAN: And then my last question is
10 that I am leading up to is does your study indicate
11 that long duration ventilation would be bad for the
12 repository because of introduction of organisms that
13 aren't there?

14 DR. HORN: Well, it is kind of a double-
15 edged thing, because you are going to be introducing
16 organisms, but you are also going to be drying things
17 out. And I think probably the dryout factor overrides
18 the introduction factor, because if you dry everything
19 out, nothing is going to grow anyway.

20 So I think during the ventilation period
21 it is a good thing in terms of corrosion, because it
22 will eliminate water.

23 MR. TYNAN: Okay. Thank you.

24 MR. LEVENSON: I have one other question.
25 You showed pictures of several different types of

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D.C. 20005-3701

1 equipment, but just to get a feel for the scope of the
2 program, how many specimens total do you think there
3 is, including your long term programs?

4 DR. HORN: I think a couple of hundred.

5 MR. LEVENSON: A couple of hundred?

6 DR. HORN: Yes.

7 MR. LEVENSON: Some of the tanks have more
8 than a hundred.

9 DR. HORN: Yes, but we go like into depth
10 on each coupon.

11 MR. LEVENSON: No, I mean the total number
12 of coupons you have in the program.

13 DR. HORN: You mean in the entire program?

14 MR. LEVENSON: Yes.

15 DR. HORN: Go ahead, Dan.

16 MR. MCCRITE: We have more than 20,000.

17 CHAIRMAN HORNBERGER: Thanks very much,
18 Joanne.

19 DR. HORN: Thank you all for your
20 attention. It has been a long day and I really
21 appreciate it. Thank you.

22 CHAIRMAN HORNBERGER: I think because we
23 had a break earlier, we are just going to continue on
24 with our agenda. Our agenda now is open, and
25 basically we are open for questions and comments on

NEAL R. GROSS

COURT REPORTERS AND TRANSCRIBERS
1323 RHODE ISLAND AVE., N.W.
WASHINGTON, D C. 20005-3701

1 anything that has been heard today and actually not
2 even restricted to anything that has been heard today.
3 We are open to hear any questions or comments that
4 people may have.

5 (No response.)

6 CHAIRMAN HORNBERGER: If not, very good,
7 and thank you all for attending. We are adjourned.

8 (Whereupon, at 5:13 p.m., the meeting was
9 adjourned, to reconvene at 8:30 a.m., on Thursday,
10 September 26, 2002.)

CERTIFICATE

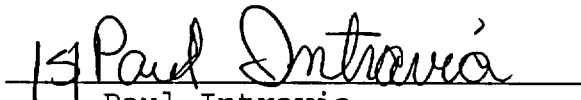

This is to certify that the attached proceedings
before the United States Nuclear Regulatory Commission
in the matter of:

Name of Proceeding: Advisory Committee on
Nuclear Waste 137th Meeting

Docket Number: N/A

Location: Las Vegas, Nevada

were held as herein appears, and that this is the
original transcript thereof for the file of the United
States Nuclear Regulatory Commission taken by me and,
thereafter reduced to typewriting by me or under the
direction of the court reporting company, and that the
transcript is a true and accurate record of the
foregoing proceedings.
